add_to_prompt_stack(prompt_driver, prompt_stack, index=None)

Add the Conversation Memory runs to the Prompt Stack by modifying the messages in place.

If autoprune is enabled, this will fit as many Conversation Memory runs into the Prompt Stack as possible without exceeding the token limit.

Parameters

Name	Type	Description	Default
prompt_driver	<a href="../../drivers/prontape.drivers.prompt.BaPromptDriver" title="BasePrompt-Driver (griptape.drivers.prompt.BaPrompt-Driver)"><code class="language-pythc	The Prompt Driver to use for token counting. 	*required*

_import_cls_rec(module_name, class_name)classmethod

Imports a class given a module name and class name.

Will recursively traverse up the module's path until it finds a package that it can import `class_name` from.

Parameters

Name	Type	Description	Default
module_name	*str*	The module name. 	*required*
class_name	*str*	The class name. 	*required*

Returns

Type	Description
<a href="serializable_mixin.mdx#griptape.mixins.serializable_mixin.SerializableMixin.type" title="type = field(default=Factory(lambda self: self.__class__.__name__, takes_self=True), kw_only=True, metadata={'serializable': True}) class-attribute instance-attribute (griptape.mixins.serializable_mixin.SerializableMixin.type)"><code class="language-python">ty	The imported class if found. Raises *ValueError* if not found.

__init_from_artifact(artifact)

Parses the input Artifact to extract either a final answer or thought and actions.

When the input Artifact is a TextArtifact, it is assumed to be the final answer. When the input Artifact is a ListArtifact, it is assumed to contain both thought and actions. Text Artifacts are parsed as the thought, and ToolAction Artifacts parsed as the actions.

Parameters

Name	Type	Description	Default
artifact	<code class="language-pythc I AudioArtifact I ListArtifact</code>	The input Artifacts. 	*required*

Returns

Type	Description
None	None

Source Code in griptape/tasks/actions_subtask.py

```

__init_from_artifact(artifact)

Parses the input Artifact to extract either a final answer or thought and actions.

When the input Artifact is a TextArtifact, it is assumed to be the final answer. When the input Artifact is a ListArtifact, it is assumed to contain both thought and actions. Text Artifacts are parsed as the thought, and ToolAction Artifacts parsed as the actions.

Parameters

Name	Type	Description	Default
artifact	<code class="language-pythc I AudioArtifact I ListArtifact</code>	The input Artifacts. 	*required*

Returns

Type	Description
None	None

dict_merge(dct, merge_dct, *, add_keys=True)

Recursive dict merge.

Inspired by :meth:`dict.update()` , instead of updating only top-level keys, dict_merge recurses down into dicts nested to an arbitrary depth, updating keys. The `merge_dct` is merged into `dct` .

This version will return a copy of the dictionary and leave the original arguments untouched.

The optional argument `add_keys` , determines whether keys which are present in `merge_dict` but not `dct` should be included in the new dict.

Parameters

Name	Type	Description	Default
dct	*Optional[dict]*	onto which the merge is executed 	*required*
merge_dct	*Optional[dict]*	dct merged into dct 	*required*
add_keys	*bool*	whether to add new keys 	*True*

Returns

Name	Type	Description
dict	*dict*	updated dict

Source Code in griptape/utils/dict_utils.py

```
def dict_merge(dct: Optional[dict], merge_dct: Optional[dict], *, add_keys: bool =␣

dict_utils

Add a key in a dictionary recursively.

Parameters

Name	Type	Description	Default
d	*Any*	The dictionary to add the key to. 	*required*
key	*str*	The key to add. 	*required*
value	*Any*	The value to add. 	*required*
criteria	*Optional[Callable[[dict], bool]]*	An optional function to determine if the key should be added. 	*None*

Source Code in griptape/utils/dict_utils.py

```
def add_key_in_dict_recursively(
    d: Any, key: str, value: Any, criteria: Optional[Callable[[dict], bool]] = None
) -> dict:
    """Add a key in a dictionary recursively.

    Args:
        d: The dictionary to add the key to.
        key: The key to add.
        value: The value to add.
        criteria: An optional function to determine if the key should be added.
    """
    if isinstance(d, dict):

        return {k: add_key_in_dict_recursively(v, key, value, criteria) for k, v in d.
↪items()}
    return d
```

dict_merge(dct, merge_dct, *, add_keys=True)

Recursive dict merge.

Inspired by :meth:`dict.update()` , instead of updating only top-level keys, dict_merge recurses down into dicts nested to an arbitrary depth, updating keys. The `merge_dct` is merged into `dct` .

This version will return a copy of the dictionary and leave the original arguments untouched.

The optional argument `add_keys` , determines whether keys which are present in `merge_dict` but not `dct` should be included in the new dict.

Parameters

Name	Type	Description	Default
dct	*Optional[dict]*	onto which the merge is executed 	*required*
merge_dct	*Optional[dict]*	dct merged into dct 	*required*
add_keys	*bool*	whether to add new keys 	*True*

Returns

Name	Type	Description
dict	*dict*	updated dict

Source Code in griptape/utils/dict_utils.py

```

11.6 Agents

11.6.1 Overview

An *agent* is the quickest way to get started with Gen AI Builder. Agents take in *Tools* and *run(prompt_input)* directly, which the agent uses to add a *Prompt Task* .

You can access the final output of the Agent by using the *Structured Output* attribute.

Agent Tools

```
from griptape.structures import Agent
from griptape.tools import CalculatorTool

agent = Agent(input="Calculate the following: {{ args[0] }}",␣
↪tools=[CalculatorTool()])

agent.run("whats 13^7?")
print("Answer:", agent.output)
```

Agent Input

```
from griptape.structures import Agent

agent = Agent(
    input="Write me a {{ args[0] }} about {{ args[1] }} and {{ args[2] }}",
)

agent.run("Haiku", "Skateboards", "Programming")
```

Configs

Overview

Gen AI Builder exposes a global singleton, *defaults_config* , which can be used to access and modify the default configurations of the framework.

To update the default configurations, simply update the fields on the `Defaults` object. Framework objects will be created with the currently set default configurations, but you can always override at the individual class level.

```
from griptape.configs import Defaults
from griptape.configs.drivers import AnthropicDriversConfig, OpenAiDriversConfig
from griptape.drivers.prompt.anthropic_prompt_driver import AnthropicPromptDriver
```

(continues on next page)

(continued from previous page)

```
from griptape.structures import Agent

Defaults.drivers_config = OpenAiDriversConfig()  # Default
openai_agent = Agent()

Defaults.drivers_config = AnthropicDriversConfig()
anthropic_agent = Agent(
    prompt_driver=AnthropicPromptDriver(model="claude-3-7-sonnet-latest"),  #␣
↪Override the default prompt driver
)
```

Drivers Configs

The *AnthropicDriversConfig* class allows for the customization of Structures within Gen AI Builder, enabling specific settings such as Drivers to be defined for Tasks.

Gen AI Builder provides predefined *AnthropicDriversConfig* 's for widely used services that provide APIs for most Driver types Gen AI Builder offers.

`DriversConfig` s can be used as a Python Context Manager using the `with` statement to temporarily change the default configurations for a block of code.

```
import schema

from griptape.configs.drivers import AnthropicDriversConfig, OpenAiDriversConfig
from griptape.drivers.prompt.anthropic import AnthropicPromptDriver
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.engines import JsonExtractionEngine
from griptape.structures import Agent
from griptape.tasks import ToolTask
from griptape.tools import ExtractionTool

with OpenAiDriversConfig():  # Agent will be created with OpenAi Drivers
    openai_agent = Agent()

with AnthropicDriversConfig():  # Agent will be created with Anthropic Drivers
    anthropic_agent = Agent(
        tasks=[
            ToolTask(
                "Extract sentiment from this text: {{ args[0] }}",
                prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1"),  # Override␣
↪this particular Tasks prompt driver
                tool=ExtractionTool(
                    extraction_engine=JsonExtractionEngine(
                        prompt_driver=AnthropicPromptDriver(  # Override this␣
↪particular Engines prompt driver
                            model="claude-3-opus-20240229"
                        ),
                        template_schema=schema.Schema({"sentiment": str}).json_schema(
↪"Output"),
                    ),
                ),
            )
```

(continues on next page)

(continued from previous page)

```
        ]
    )

anthropic_agent.run("Hello, I am happy!")
```

OpenAI

The *OpenAI Driver config* provides default Drivers for OpenAI's APIs. This is the default config for all Structures.

```
from griptape.configs import Defaults
from griptape.configs.drivers import OpenAiDriversConfig
from griptape.structures import Agent

Defaults.drivers_config = OpenAiDriversConfig()

agent = Agent()
```

Azure OpenAI

The *Azure OpenAI Driver config* provides default Drivers for Azure's OpenAI APIs.

```
import os

from griptape.configs import Defaults
from griptape.configs.drivers import AzureOpenAiDriversConfig
from griptape.structures import Agent

Defaults.drivers_config = AzureOpenAiDriversConfig(
    azure_endpoint=os.environ["AZURE_OPENAI_ENDPOINT_1"], api_key=os.environ["AZURE_
↪OPENAI_API_KEY_1"]
)

agent = Agent()
```

Amazon Bedrock

The *Amazon Bedrock Driver config* provides default Drivers for Amazon Bedrock's APIs.

```
import os

import boto3

from griptape.configs import Defaults
from griptape.configs.drivers import AmazonBedrockDriversConfig
from griptape.structures import Agent

Defaults.drivers_config = AmazonBedrockDriversConfig(
    session=boto3.Session(
        region_name=os.environ["AWS_DEFAULT_REGION"],
        aws_access_key_id=os.environ["AWS_ACCESS_KEY_ID"],
        aws_secret_access_key=os.environ["AWS_SECRET_ACCESS_KEY"],
```

(continues on next page)

(continued from previous page)

```
    )
)

agent = Agent()
```

Google

The *Google Driver config* provides default Drivers for Google's Gemini APIs.

```
from griptape.configs import Defaults
from griptape.configs.drivers import GoogleDriversConfig
from griptape.structures import Agent

Defaults.drivers_config = GoogleDriversConfig()

agent = Agent()
```

Anthropic

The *Anthropic Driver config* provides default Drivers for Anthropic's APIs.

```
from griptape.configs import Defaults
from griptape.configs.drivers import AnthropicDriversConfig
from griptape.structures import Agent

Defaults.drivers_config = AnthropicDriversConfig()

agent = Agent()
```

Cohere

The *Cohere Driver config* provides default Drivers for Cohere's APIs.

```
import os

from griptape.configs import Defaults
from griptape.configs.drivers import CohereDriversConfig
from griptape.structures import Agent

Defaults.drivers_config = CohereDriversConfig(api_key=os.environ["COHERE_API_KEY"])

agent = Agent()
```

Custom

You can create your own *AnthropicDriversConfig* by overriding relevant Drivers. The *AnthropicDriversConfig* class includes "Dummy" Drivers for all types, which throw a *DummyError* if invoked without being overridden. This approach ensures that you are informed through clear error messages if you attempt to use Structures without proper Driver configurations.

```
import os

from griptape.configs import Defaults
from griptape.configs.drivers import DriversConfig
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver
from griptape.drivers.prompt.anthropic import AnthropicPromptDriver
from griptape.structures import Agent

Defaults.drivers_config = DriversConfig(
    prompt_driver=AnthropicPromptDriver(
        model="claude-3-sonnet-20240229",
        api_key=os.environ["ANTHROPIC_API_KEY"],
    ),
    embedding_driver=OpenAiEmbeddingDriver(),
)

agent = Agent()
```

Logging Config

Gen AI Builder provides a predefined *LoggingConfig* 's for easily customizing the logging events that the framework emits. In order to customize the logger, the logger can be fetched by using the `Defaults.logging.logger_name`.

```
import logging

from griptape.configs import Defaults
from griptape.configs.drivers import OpenAiDriversConfig
from griptape.configs.logging import TruncateLoggingFilter
from griptape.structures import Agent

Defaults.drivers_config = OpenAiDriversConfig()

logger = logging.getLogger(Defaults.logging_config.logger_name)
logger.setLevel(logging.ERROR)
logger.addFilter(TruncateLoggingFilter(max_log_length=100))

agent = Agent()
```

Debug Logs

You can enable debug logs to view more granular information such as request/response payloads.

```
import logging

from griptape.configs import Defaults
from griptape.configs.logging import JsonFormatter
from griptape.structures import Agent

logger = logging.getLogger(Defaults.logging_config.logger_name)
logger.setLevel(logging.DEBUG)
logger.handlers[0].setFormatter(JsonFormatter())
```

(continues on next page)

(continued from previous page)

```
agent = Agent()

agent.run("Hello world!")
```

Loading/Saving Configs

You can serialize and deserialize Driver Configs using the *actions_to_json()* and *from_json()* methods.

```
from pathlib import Path

from griptape.configs import Defaults
from griptape.configs.drivers import DriversConfig
from griptape.structures import Agent

config_file = "config.json"

#  Save config

config_text = Defaults.drivers_config.to_json()
Path(config_file).write_text(config_text)

#  Load config

config_text = Path(config_file).read_text()
Defaults.drivers_config = DriversConfig.from_json(config_text)

agent = Agent()
```

Conversation Memory

Overview

You can use Conversation Memory to give Gen AI Builder Structures the ability to keep track of the conversation across runs. All structures are created with *AmazonDynamoDbConversationMemoryDriver* by default.

Example

```
from griptape.structures import Agent

agent = Agent()

agent.run("My favorite animal is a Liger.")
agent.run("What is my favorite animal?")
```

You can disable conversation memory in any structure by setting it to `None` :

```
from griptape.structures import Agent

Agent(conversation_memory=None)
```

Interaction With Structures

Per Structure

By default, Conversation Memory *store(runs, metadata)* are created for each run of the structure. Gen AI Builder takes the Structure's *base_audio_input_task* 's input and the *output_task* 's output, storing them in the Run. Tasks that are neither the input task nor the output task are not stored in the Run.

```
from griptape.structures import Pipeline
from griptape.tasks import PromptTask

pipeline = Pipeline(
    tasks=[
        PromptTask("Respond to this request: {{ args[0] }}", id="input"),
        PromptTask("Improve the writing of this: {{ parent_output }}", id="improve"),
        PromptTask("Output this as a pirate: {{ parent_output }}", id="output"),
    ]
)

pipeline.run("My favorite animal is a Liger.")

if pipeline.conversation_memory is not None:
    for run in pipeline.conversation_memory.runs:
        print("Input", run.input.value)
        print("Output", run.output.value)
        print("\n\n")
```

In this example, the `improve` Task is "forgotten" after the Structure's run is finished. This approach allows you to perform intermediary work within a Structure without it being stored in, and potentially cluttering, Conversation Memory.

Per Task

You can change when Conversation Memory Runs are created by modifying *Structure.conversation_memory_strategy* from the default `per_structure` to `per_task` .

```
from griptape.structures import Pipeline
from griptape.tasks import PromptTask

pipeline = Pipeline(
    conversation_memory_strategy="per_task",
    tasks=[
        PromptTask("Respond to this request: {{ args[0] }}", id="input"),
        PromptTask("Improve the writing", id="improve"),
        PromptTask("Respond as a pirate", id="output"),
    ],
)

pipeline.run("My favorite animal is a Liger.")

if pipeline.conversation_memory is not None:
    for run in pipeline.conversation_memory.runs:
        print("Input", run.input.value)
        print("Output", run.output.value)
```

(continues on next page)

(continued from previous page)

```
        print("\n\n")
```

Now, each *Task* creates a Conversation Memory Run when it runs. This eliminates the need to feed the output of Tasks into each other using context variables like `{{ parent_output }}` since the output of the previous Task is stored in Conversation Memory and loaded when the next Task runs.

To blend the two approaches, you can disable Conversation Memory on individual tasks by setting *PromptTask.conversation_memory* to `None`.

```
from griptape.structures import Pipeline
from griptape.tasks import PromptTask

pipeline = Pipeline(
    conversation_memory_strategy="per_task",
    tasks=[
        PromptTask("Respond to this request: {{ args[0] }}", id="input"),
        PromptTask("Improve the writing of this: {{ parent_output }}", id="improve",␣
↪conversation_memory=None),
        PromptTask("Respond as a pirate", id="output"),
    ],
)

pipeline.run("My favorite animal is a Liger.")

if pipeline.conversation_memory is not None:
    for run in pipeline.conversation_memory.runs:
        print("Input", run.input.value)
        print("Output", run.output.value)
        print("\n\n")
```

Types of Memory

Gen AI Builder provides several types of Conversation Memory to fit various use-cases.

Conversation Memory

AmazonDynamoDbConversationMemoryDriver will keep track of the full task input and output for all runs.

```
from griptape.memory.structure import ConversationMemory
from griptape.structures import Agent

agent = Agent(conversation_memory=ConversationMemory())

agent.run("Hello!")

print(agent.conversation_memory)
```

You can set the *max_runs* parameter to limit how many runs are kept in memory.

```
from griptape.memory.structure import ConversationMemory
from griptape.structures import Agent

```

(continues on next page)

(continued from previous page)

```
conversation_memory = ConversationMemory(max_runs=2)
agent = Agent(conversation_memory=conversation_memory)

agent.run("Run 1")
agent.run("Run 2")
agent.run("Run 3")
agent.run("Run 4")
agent.run("Run 5")

print(conversation_memory.runs[0].input == "run4")
print(conversation_memory.runs[1].input == "run5")
```

Summary Conversation Memory

SummaryConversationMemory will progressively summarize task input and output of runs.

You can choose to offset which runs are summarized with the query_vector(vector, *, count=None, namespace=None, include_vectors=False, offset=None, **kwargs) parameter.

```
from griptape.memory.structure import SummaryConversationMemory
from griptape.structures import Agent
from griptape.utils import Conversation

agent = Agent(conversation_memory=SummaryConversationMemory(offset=2))

agent.run("Hello my name is John?")
agent.run("What is my name?")
agent.run("My favorite color is blue.")

print(Conversation(agent.conversation_memory))
```

Observability

Overview

The *Observability* context manager sends telemetry (metrics and traces) for all functions and methods annotated with the `@observable` decorator to a destination of your choice. This is useful for monitoring and debugging your application.

Observability is completely optional. To opt in, wrap your application code with the *Observability* context manager, for example:

```
from griptape.drivers.observability.griptape_cloud import␣
↪GriptapeCloudObservabilityDriver
from griptape.observability import Observability
from griptape.structures import Agent

observability_driver = GriptapeCloudObservabilityDriver()

with Observability(observability_driver=observability_driver):
    # Important! Only code within this block is subject to observability
    agent = Agent()
    agent.run("Name the five greatest rappers of all time")
```

Tracing Custom Code

All functions and methods annotated with the `@observable` decorator will be traced when invoked within the context of the *Observability* context manager, including functions and methods defined outside of the Gen AI Builder SDK. Thus to trace custom code, you just need to add the `@observable` decorator to your function or method, then invoke it within the *Observability* context manager.

For example:

```
import time

from griptape.common import observable
from griptape.drivers.observability.griptape_cloud import␣
↪GriptapeCloudObservabilityDriver
from griptape.observability import Observability

#  Decorate a function

@observable
def my_function() -> None:
    time.sleep(3)

class MyClass:
    # Decorate a method
    @observable
    def my_method(self) -> None:
        time.sleep(1)
        my_function()
        time.sleep(2)

observability_driver = GriptapeCloudObservabilityDriver()

#  When invoking the instrumented code from within the Observability context manager,␣
↪the

#  telemetry for the custom code will be sent to the destination specified by the␣
↪driver.

with Observability(observability_driver=observability_driver):
    my_function()
    MyClass().my_method()
```

Pipelines

Overview

A *HuggingFace Pipelines* is very similar to an *agent* , but allows for multiple tasks.

You can access the final output of the Pipeline by using the *Structured Output* attribute.

Context

Pipelines have access to the following *RAG Context* variables in addition to the *base context* .

- `task_outputs` : dictionary containing mapping of all task IDs to their outputs.
- `parent_output` : output from the parent task if one exists, otherwise `None` .
- `parent` : parent task if one exists, otherwise `None` .
- `child` : child task if one exists, otherwise `None` .

Pipeline

```
from griptape.structures import Pipeline
from griptape.tasks import PromptTask

pipeline = Pipeline()

pipeline.add_tasks(
    # take the first argument from the pipeline `run` method
    PromptTask("{{ args[0] }}"),
    # take the output from the previous task and insert it into the prompt
    PromptTask("Say the following like a pirate: {{ parent_output }}"),
)

pipeline.run("Write me a haiku about sailing.")
```

Rulesets

Overview

A *Ruleset* can be used to define *Ruleset* s for *Structures* and add_tasks(*tasks) . Gen AI Builder places Rules into the LLM's system prompt for strong control over the output.

Types of Rules

Rule

Ruleset s shape the LLM's behavior by defining specific guidelines or instructions for how it should interpret and respond to inputs. Rules can be used to modify language style, tone, or even behavior based on what you define.

> **Tip**
>
> Avoid writing large amounts of text in a single Rule. Breaking down your Rules generally helps the LLM follow them more effectively. Additionally, it makes it easier to evaluate the Rule's effectiveness using tools like the *Eval Engine* . If you have an existing system prompt, consider *overriding the default system prompt* instead.

```
from griptape.rules import Rule, Ruleset
from griptape.structures import Agent

pipeline = Agent(
    rulesets=[
```

(continues on next page)

(continued from previous page)

```
        Ruleset(
            name="Personality",
            rules=[Rule("Talk like a pirate.")],
        ),
    ]
)

pipeline.run("Hi there! How are you?")
```

Json Schema

> **Tip**
>
> *Structured Output* provides a more robust solution for having the LLM generate structured output.

JsonSchemaRule s defines a structured format for the LLM's output by providing a JSON schema. This is particularly useful when you need the LLM to return well-formed data, such as JSON objects, with specific fields and data types.

```
import json

import schema

from griptape.rules.json_schema_rule import JsonSchemaRule
from griptape.structures import Agent

agent = Agent(
    rules=[
        JsonSchemaRule(
            schema.Schema({"answer": str, "relevant_emojis": schema.Schema(["str"])}).
↪json_schema("Output Format")
        )
    ]
)

output = agent.run("What is the sentiment of this message?: I am so happy!").output

print(json.dumps(json.loads(output.value), indent=2))
```

Although Gen AI Builder leverages the `schema` library, you're free to use any JSON schema generation library to define your schema!

For example, using `pydantic` :

```
from __future__ import annotations

import pydantic

from griptape.rules.json_schema_rule import JsonSchemaRule
from griptape.structures import Agent

class SentimentModel(pydantic.BaseModel):
```

(continues on next page)

(continued from previous page)

```
    answer: str
    relevant_emojis: list[str]

agent = Agent(rules=[JsonSchemaRule(SentimentModel.model_json_schema())])

output = agent.run("What is the sentiment of this message?: I am so happy!").output

sentiment_analysis = SentimentModel.model_validate_json(output.value)

#  Autocomplete via dot notation 

print(sentiment_analysis.answer)
print(sentiment_analysis.relevant_emojis)
```

Structure

Rulesets

You can define a Ruleset at the Structure level if you need to have certain behaviors across all Tasks.

```
from griptape.rules import Rule, Ruleset
from griptape.structures import Pipeline
from griptape.tasks import PromptTask

pipeline = Pipeline(
    rulesets=[
        Ruleset(
            name="Employment",
            rules=[
                Rule("Behave like a polite customer support agent"),
                Rule("Act like you work for company SkaterWorld, Inc."),
                Rule("Discuss only topics related to skateboarding"),
                Rule("Limit your response to fewer than 5 sentences."),
            ],
        ),
        Ruleset(
            name="Background",
            rules=[
                Rule("Your name is Todd"),
            ],
        ),
    ]
)

pipeline.add_tasks(
    PromptTask(input="Respond to this users question: {{ args[0] }}"),
    PromptTask(input="Extract keywords from this response: {{ parent_output }}"),
)

pipeline.run("How do I do a kickflip?")
```

Rules

You can pass *Ruleset* directly to the Structure to have a Ruleset created for you.

```
from griptape.rules import Rule
from griptape.structures import Pipeline
from griptape.tasks import PromptTask

pipeline = Pipeline(
    rules=[
        Rule("Respond only using emojis"),
    ],
)

pipeline.add_tasks(
    PromptTask("Respond to this question from the user: {{ args[0] }}"),
    PromptTask("How would you rate your response (1-5)? 1 being bad, 5 being good.␣
↪Response: {{parent_output}}"),
)

pipeline.run("How do I bake a cake?")
```

Task

Rulesets

You can define a Ruleset at the Task level if you need to have different behaviors per Task.

```
from griptape.rules import Rule, Ruleset
from griptape.structures import Pipeline
from griptape.tasks import PromptTask

pipeline = Pipeline()

pipeline.add_tasks(
    PromptTask(
        input="Respond to the following prompt: {{ args[0] }}",
        rulesets=[
            Ruleset(
                name="Emojis",
                rules=[
                    Rule("Respond using uppercase characters only."),
                ],
            )
        ],
    ),
    PromptTask(
        input="Determine the sentiment of the following text: {{ parent_output }}",
        rulesets=[
            Ruleset(
                name="Diacritic",
                rules=[
                    Rule("Respond using diacritic characters only."),
```

(continues on next page)

(continued from previous page)

```
                ],
            )
        ],
    ),
)

pipeline.run("I love skateboarding!")
```

Rules

You can pass *Ruleset* directly to the Task to have a Ruleset created for you.

```
from griptape.rules import Rule
from griptape.structures import Pipeline
from griptape.tasks import PromptTask

pipeline = Pipeline()

pipeline.add_tasks(
    PromptTask(
        rules=[
            Rule("Write your answer in json with a single key emoji_response"),
            Rule("Respond only using emojis"),
        ],
    ),
)

pipeline.run("How are you?")
```

Overriding System Prompts

While Rulesets are the preferred way to steer LLM output, sometimes you may want to fully override the system prompt.

```
from textwrap import dedent

from griptape.rules import Rule
from griptape.structures import Pipeline
from griptape.tasks.prompt_task import PromptTask

pipeline = Pipeline(
    tasks=[
        PromptTask(
            rules=[Rule("Your favorite color is blue")],  # Will be ignored!
            generate_system_template=lambda _: dedent("""
                Employment:
                    - Behave like a polite customer support agent
                    - Act like you work for company SkaterWorld, Inc.
                    - Discuss only topics related to skateboarding
                    - Limit your response to fewer than 5 sentences.
```

(continues on next page)

(continued from previous page)

```
                Background:
                    - Your name is Todd
                """),
        )
    ]
)

pipeline.run("What is your name and favorite color?")
```

Note that when overriding the system prompt, it is your responsibility to integrate anything that goes in *by default* . You can achieve this by appending the default system prompt to your custom prompt like so:

```
from textwrap import dedent

from griptape.rules import Rule
from griptape.structures import Pipeline
from griptape.tasks.prompt_task import PromptTask

pipeline = Pipeline(
    tasks=[
        PromptTask(
            rules=[Rule("Your favorite color is blue")],
            generate_system_template=lambda task: dedent(
                """
                Employment:
                    - Behave like a polite customer support agent
                    - Act like you work for company SkaterWorld, Inc.
                    - Discuss only topics related to skateboarding
                    - Limit your response to fewer than 5 sentences.

                Background:
                    - Your name is Todd
                """
                + task.default_generate_system_template(task)
            ),
        )
    ]
)

pipeline.run("What is your name and favorite color?")
```

Task Memory and Off Prompt

Overview

Task Memory is a powerful feature of Gen AI Builder that allows you to control where the data returned by *Tools* is stored. This is useful in the following scenarios:

- **Security requirements**: many organizations don't want data to leave their cloud for regulatory and security reasons.
- **Long textual content**: when textual content returned by Tools can't fit in the token limit, it's often useful to perform actions on it as a separate operation, not through the main LLM.

- **Non-textual content**: Tools can generate images, videos, PDFs, and other non-textual content that can be stored in Task Memory and acted upon later by other Tools.

> **Tip**
>
> Running into issue with Task Memory? Check out the *Task Memory Considerations* section for some common pitfalls.

Off Prompt

You can enable or disable sending a Tool's results to Task Memory with the `off_prompt` parameter. By default, all Tools have `off_prompt` set to `False` making this an opt-in feature. When `off_prompt` is set to `True`, the Tool will store its output in Task Memory. When `off_prompt` is set to `False`, the Tool will return its output directly to the LLM.

Lets look at a simple example where `off_prompt` is set to `False`:

```
from griptape.structures import Agent
from griptape.tools import CalculatorTool

#  Create an agent with the CalculatorTool tool

agent = Agent(tools=[CalculatorTool(off_prompt=False)])

agent.run("What is the square root of 12345?")
```

Since the result of the CalculatorTool Tool is neither sensitive nor too large, we can set `off_prompt` to `False` and not use Task Memory.

Let's explore what happens when `off_prompt` is set to `True`:

```
from griptape.structures import Agent
from griptape.tools import CalculatorTool

#  Create an agent with the CalculatorTool tool

agent = Agent(tools=[CalculatorTool(off_prompt=True)])

agent.run("What is the square root of 12345?")
```

When we set `off_prompt` to `True`, the Agent does not function as expected, even generating an error. This is because the Calculator output is being stored in Task Memory but the Agent has no way to access it. To fix this, we need a *Tool that can read from Task Memory* such as the `PromptSummaryTool`. This is an example of *Not Providing a Task Memory Compatible Tool*.

Prompt Summary Tool

The *PromptSummaryTool* is a Tool that allows an Agent to summarize the Artifacts in Task Memory. It has the following methods:

Let's add `PromptSummaryTool` to the Agent and run the same task. Note that on the `PromptSummaryTool` we've set `off_prompt` to `False` so that the results of the query can be returned directly to the LLM. If we had kept it as `True`, the results would have been stored back Task Memory which would've put us back to square one. See *Task Memory Looping* for more information on this scenario.

```
from griptape.structures import Agent
from griptape.tools import CalculatorTool, PromptSummaryTool

#  Create an agent with the Calculator tool

agent = Agent(tools=[CalculatorTool(off_prompt=True), PromptSummaryTool(off_
↪prompt=False)])

agent.run("What is the square root of 12345?")
```

While this fixed the problem, it took a handful more steps than when we just had `CalculatorTool()`. Something like a basic calculation is an instance of where *Task Memory May Not Be Necessary*. Let's look at a more complex example where Task Memory shines.

Large Data

Let's say we want to query the contents of a very large webpage.

```
from griptape.structures import Agent
from griptape.tools import WebScraperTool

#  Create an agent with the WebScraperTool tool

agent = Agent(tools=[WebScraperTool()])

agent.run(
    "According to this page https://en.wikipedia.org/wiki/Elden_Ring, how many copies␣
↪of Elden Ring have been sold?"
)
```

When running this example, we get the following error:

```
[04/26/24 13:20:02] ERROR    PromptTask 67e2f907f95d4850ae79f9da67df54c1
                             Error code: 400 - {error: {message: "This models maximum␣
↪context length is 8192 tokens. However, your messages resulted in 73874 tokens.
                             Please reduce the length of the messages.", type:␣
↪invalid_request_error, param: messages, code: context_length_exceeded}}
```

This is because the content of the webpage is too large to fit in the LLM's input token limit. We can fix this by storing the content in Task Memory, and then querying it with the `QueryTool`. Note that we're setting `off_prompt` to `False` on the `QueryTool` so that the *queried* content can be returned directly to the LLM.

```
from griptape.structures import Agent
from griptape.tools import QueryTool, WebScraperTool

agent = Agent(
    tools=[
        WebScraperTool(off_prompt=True),
        QueryTool(off_prompt=False),
    ]
)

agent.run(
```

(continues on next page)

(continued from previous page)

```
    "According to this page https://en.wikipedia.org/wiki/Elden_Ring, how many copies␣
↪of Elden Ring have been sold?"
)
```

And now we get the expected output.

```
[08/12/24 14:56:29] INFO     Subtask 8669ee523bb64550850566011bcd14e2
                             Response: "Elden Ring" sold 13.4 million copies␣
↪worldwide by the end of March 2022 and 25 million by June 2024. The downloadable␣
↪content (DLC)
                             "Shadow of the Erdtree" sold five million copies within␣
↪three days of its release.
[08/12/24 14:56:30] INFO     PromptTask d3ce58587dc944b0a30a205631b82944
                             Output: Elden Ring sold 13.4 million copies worldwide by␣
↪the end of March 2022 and 25 million by June 2024.
```

Sensitive Data

Because Task Memory splits up the storage and retrieval of data, you can use different models for each step.

Here is an example where we use GPT-4 to orchestrate the Tools and store the data in Task Memory, and Anthropic's Claude 3 Haiku model to query the raw content. In this example, GPT-4 *never* sees the contents of the page, only that it was stored in Task Memory. Even the query results generated by the Haiku model are stored in Task Memory so that the `FileManagerTool` can save the results to disk without GPT-4 ever seeing them.

```
from griptape.configs import Defaults
from griptape.configs.drivers import OpenAiDriversConfig
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver
from griptape.drivers.prompt.amazon_bedrock import AmazonBedrockPromptDriver
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.drivers.vector.local import LocalVectorStoreDriver
from griptape.structures import Agent
from griptape.tools import FileManagerTool, QueryTool, WebScraperTool

Defaults.drivers_config = OpenAiDriversConfig(
    prompt_driver=OpenAiChatPromptDriver(model="gpt-4"),
)

vector_store_driver = LocalVectorStoreDriver(embedding_driver=OpenAiEmbeddingDriver())

agent = Agent(
    tools=[
        WebScraperTool(off_prompt=True),
        QueryTool(
            off_prompt=True,
            prompt_driver=AmazonBedrockPromptDriver(model="anthropic.claude-3-haiku-
↪20240307-v1:0"),
        ),
        FileManagerTool(off_prompt=True),
    ],
)
```

(continues on next page)

(continued from previous page)

```
agent.run(
    "Use this page https://en.wikipedia.org/wiki/Elden_Ring to find how many copies␣
↪of Elden Ring have been sold, and then save the result to a file."
)
```

Tools That Can Read From Task Memory

As seen in the previous example, certain Tools are designed to read directly from Task Memory. This means that you can use these Tools to interact with the data stored in Task Memory without needing to pass it through the LLM.

Today, these include:

- `:ref:`PromptSummaryTool <PromptSummaryTool>``
- `:ref:`ExtractionTool <ExtractionTool>``
- `:ref:`RagTool <RagTool>``
- `:ref:`FileManagerTool <FileManagerTool>``
- `:ref:`ImageQueryTool <ImageQueryTool>``

Task Memory Considerations

Task Memory is a powerful feature of Gen AI Builder, but with great power comes great responsibility. Here are some things to keep in mind when using Task Memory:

Tool Return Types

Gen AI Builder will only store Artifacts in Task Memory that have been explicitly defined in the `artifact_storages` parameter of the `TaskMemory` object. If you try to store an Artifact that is not defined in `artifact_storages`, Gen AI Builder will raise an error. The exception to this is `InfoArtifact` s and `ErrorArtifact` s. Gen AI Builder will never store these Artifacts store in Task Memory. By default, Gen AI Builder will store `TextArtifact` 's, `BlobArtifact` 's in Task Memory. Additionally, Gen AI Builder will also store the elements of `ListArtifact` 's as long as they are of a supported Artifact type.

Not Providing a Task Memory Compatible Tool

When using Task Memory, make sure that you have at least one Tool that can read from Task Memory. If you don't, the data stored in Task Memory will be inaccessible to the Agent and it may hallucinate Tool Activities.

```
from griptape.structures import Agent
from griptape.tools import WebScraperTool

agent = Agent(
    tools=[
        WebScraperTool(off_prompt=True)  # `off_prompt=True` will store the data in␣
↪Task Memory
        # Missing a Tool that can read from Task Memory
    ]
```

(continues on next page)

(continued from previous page)

```
)
agent.run(
    "According to this page https://en.wikipedia.org/wiki/San_Francisco, what is the␣
↪population of San Francisco?"
)
```

Task Memory Looping

An improper configuration of Tools can lead to the LLM using the Tools in a loop. For example, if you have a Tool that stores data in Task Memory and another Tool that queries that data from Task Memory (*Tools That Can Read From Task Memory*), make sure that the query Tool does not store the data back in Task Memory. This can create a loop where the same data is stored and queried over and over again.

```
from griptape.structures import Agent
from griptape.tools import PromptSummaryTool, WebScraperTool

agent = Agent(
    tools=[
        WebScraperTool(off_prompt=True),  # This tool will store the data in Task␣
↪Memory
        PromptSummaryTool(
            off_prompt=True
        ),  # This tool will store the data back in Task Memory with no way to get it␣
↪out
    ]
)
agent.run(
    "According to this page https://en.wikipedia.org/wiki/Dark_forest_hypothesis,␣
↪what is the Dark Forest Hypothesis?"
)
```

Task Memory May Not Be Necessary

Task Memory may not be necessary for all use cases. If the data returned by a Tool is not sensitive, not too large, and does not need to be acted upon by another Tool, you can leave the default of `off_prompt` to `False` and return the data directly to the LLM.

```
from griptape.structures import Agent
from griptape.tools import CalculatorTool

agent = Agent(
    tools=[
        CalculatorTool()  # Default value of `off_prompt=False` will return the data␣
↪directly to the LLM
    ]
)
agent.run("What is 10 ^ 3, 55 / 23, and 12345 * 0.5?")
```

Tasks

Overview

A add_tasks(*tasks) is a purpose-built abstraction for the Large Language Model (LLM). Gen AI Builder offers various types of Tasks, each suitable for specific use cases.

Context

Tasks that take input have a field *run(prompt_input)* which lets you define the Task objective. Within the *run(prompt_input)* , you can access the following *RAG Context* variables:

- `args` : an array of arguments passed to the `.run()` method.
- `structure` : the structure that the task belongs to.
- user defined context variables

Additional *RAG Context* variables may be added based on the Structure running the task.

```
from griptape.structures import Agent
from griptape.tasks import PromptTask

agent = Agent()
agent.add_task(
    PromptTask(
        "Respond to the users following question {{ args[0] }} in the language {
↪{preferred_language}} and tone {{tone}}.",
        context={"preferred_language": "ENGLISH", "tone": "PLAYFUL"},
    )
)

agent.run("How do I bake a cake?")
```

Hooks

All Tasks implement *RunnableMixin* which provides `on_before_run` and `on_after_run` hooks for the Task lifecycle.

These hooks can be used to perform actions before and after the Task is run. For example, you can mask sensitive information before running the Task, and transform the output after the Task is run.

```
import json
import re

from griptape.structures import Agent
from griptape.tasks import PromptTask
from griptape.tasks.base_task import BaseTask

SSN_PATTERN = re.compile(r"\b\d{3}-\d{2}-\d{4}\b")

original_input = None

def on_before_run(task: BaseTask) -> None:
    global original_input  # noqa: PLW0603
```

(continues on next page)

(continued from previous page)

```
    original_input = task.input.value

    if isinstance(task, PromptTask):
        task.input = SSN_PATTERN.sub("xxx-xx-xxxx", task.input.value)

def on_after_run(task: BaseTask) -> None:
    if task.output is not None:
        task.output.value = json.dumps(
            {"original_input": original_input, "masked_input": task.input.value,
↪"output": task.output.value}, indent=2
        )

agent = Agent(
    tasks=[
        PromptTask(
            "Respond to this user: {{ args[0] }}",
            on_before_run=on_before_run,
            on_after_run=on_after_run,
        )
    ]
)
agent.run("Hello! My favorite color is blue, and my social security number is 123-45-
↪6789.")
```

Prompt Task

For general-purpose interaction with LLMs, use the *PromptTask* :

```
from griptape.structures import Agent
from griptape.tasks import PromptTask

agent = Agent()
agent.add_task(
    # take the first argument from the agent `run` method
    PromptTask("Respond to the following request: {{ args[0] }}"),
)

agent.run("Write me a haiku")
```

Tools

You can pass in one or more Tools which the LLM will decide to use through Chain of Thought (CoT) reasoning. Because tool execution uses CoT, it is recommended to only use with very capable models.

```
from griptape.structures import Agent
from griptape.tasks import PromptTask
from griptape.tools import FileManagerTool, PromptSummaryTool, WebScraperTool

agent = Agent()
agent.add_task(
    PromptTask(
```

(continues on next page)

(continued from previous page)

```
        "Load https://www.griptape.ai, summarize it, and store it in a file called␣
↪griptape.txt",
        tools=[WebScraperTool(off_prompt=True), FileManagerTool(off_prompt=True),␣
↪PromptSummaryTool(off_prompt=True)],
    ),
)

agent.run()
```

Reflect On Tool Use

By default, Gen AI Builder will pass the results of Tool runs back to the LLM for reflection. This enables the LLM to reason about the results and potentially use additional tools.

However, there may be times where you may want the LLM to give you back the results directly, without reflection. You can disable this behavior by setting *reflect_on_tool_use* to `False` .

```
from griptape.artifacts.list_artifact import ListArtifact
from griptape.drivers.web_search.duck_duck_go import DuckDuckGoWebSearchDriver
from griptape.tasks import PromptTask
from griptape.tools import WebScraperTool, WebSearchTool

search_task = PromptTask(
    tools=[WebSearchTool(web_search_driver=DuckDuckGoWebSearchDriver())],
    reflect_on_tool_use=False,
)
search_results = search_task.run("Do two searches, one for vim and one for emacs.")

#  When disabling `reflect_on_tool_use`, the Tasks results will be returned as a␣
↪ListArtifact.

#  Each item in the ListArtifact will be the result of a single tool execution.

if isinstance(search_results, ListArtifact):
    for result in search_results:
        print(result)

scrape_task = PromptTask(
    tools=[WebScraperTool()],
    reflect_on_tool_use=True,
)

#  If we dont care about the individual results, we can join them back together␣
↪before passing to the next task.

answer = scrape_task.run(["Compare and contrast vim and emacs: ", search_results.to_
↪text()])
```

Important

Disabling reflection will prevent the LLM from using one Tool to inform the use of another Tool. Instead, you

must coordinate the Tool uses yourself.

Images

If the model supports it, you can also pass image inputs:

```
from griptape.loaders import ImageLoader
from griptape.structures import Agent

agent = Agent()

image_artifact = ImageLoader().load("tests/resources/mountain.jpg")

agent.run([image_artifact, "Whats in this image?"])
```

Tool Task

Warning

ToolTask is deprecated and will be removed in a future version. Use *Prompt Task* with *reflect_on_tool_use* set to *False* instead.

Another way to use *Gen AI Builder Tools* , is with a *Tool Task* . This Task takes in a single Tool which the LLM will use without Chain of Thought (CoT) reasoning. Because this Task does not use CoT, it is better suited for less capable models.

```
from griptape.structures import Agent
from griptape.tasks import ToolTask
from griptape.tools import CalculatorTool

#  Initialize the agent and add a task

agent = Agent()
agent.add_task(ToolTask(tool=CalculatorTool()))

#  Run the agent with a prompt

agent.run("Give me the answer for 5*4.")
```

Extraction Task

To extract information from text, use an *ExtractionTask* . This Task takes an *Extraction Engines* , and a set of arguments specific to the Engine.

CSV Extraction

```
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.engines import CsvExtractionEngine
from griptape.structures import Agent
```

(continues on next page)

(continued from previous page)

```
from griptape.tasks import ExtractionTask

#  Instantiate the CSV extraction engine

csv_extraction_engine = CsvExtractionEngine(
    prompt_driver=OpenAiChatPromptDriver(model="gpt-3.5-turbo"), column_names=["Name",
↪ "Age", "Address"]
)

#  Define some unstructured data and columns

csv_data = """
Alice, 28, lives in New York.
Bob, 35 lives in California.
Charlie is 40 and lives in Texas.
"""

#  Create an agent and add the ExtractionTask to it

agent = Agent()
agent.add_task(
    ExtractionTask(
        extraction_engine=csv_extraction_engine,
    )
)

#  Run the agent

agent.run(csv_data)
```

JSON Extraction

```
from schema import Schema

from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.engines import JsonExtractionEngine
from griptape.structures import Agent
from griptape.tasks import ExtractionTask

#  Instantiate the json extraction engine

json_extraction_engine = JsonExtractionEngine(
    prompt_driver=OpenAiChatPromptDriver(model="gpt-3.5-turbo"),
    template_schema=Schema({"users": [{"name": str, "age": int, "location": str}]}).
↪json_schema("UserSchema"),
)

#  Define some unstructured data and a schema

json_data = """
Alice (Age 28) lives in New York.
```

(continues on next page)

(continued from previous page)

```
Bob (Age 35) lives in California.
"""

agent = Agent()
agent.add_task(
    ExtractionTask(
        extraction_engine=json_extraction_engine,
    )
)

#  Run the agent

agent.run(json_data)
```

Text Summary Task

To summarize a text, use the *TextSummaryTask* . This Task takes an *Summarization Engine* , and a set of arguments to the engine.

```
from griptape.structures import Agent
from griptape.tasks import TextSummaryTask

#  Create a new agent

agent = Agent()

#  Add the TextSummaryTask to the agent

agent.add_task(TextSummaryTask())

#  Run the agent

agent.run(
    "Artificial Intelligence (AI) is a branch of computer science that deals with "
    "creating machines capable of thinking and learning. It encompasses various␣
↪fields "
    "such as machine learning, neural networks, and deep learning. AI has the␣
↪potential "
    "to revolutionize many sectors, including healthcare, finance, and transportation.
↪ "
    "Our life in this modern age depends largely on computers. It is almost␣
↪impossible "
    "to think about life without computers. We need computers in everything that we␣
↪use "
    "in our daily lives. So it becomes very important to make computers intelligent␣
↪so "
    "that our lives become easy. Artificial Intelligence is the theory and␣
↪development "
    "of computers, which imitates the human intelligence and senses, such as visual "
    "perception, speech recognition, decision-making, and translation between␣
↪languages."
    " Artificial Intelligence has brought a revolution in the world of technology. "
```

(continues on next page)

(continued from previous page)

```
)
```

RAG Task

To query text, use the *RagTask* . This task takes a *RAG Engine* , and a set of arguments specific to the engine.

```
from griptape.artifacts import TextArtifact
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.drivers.vector.local import LocalVectorStoreDriver
from griptape.engines.rag import RagEngine
from griptape.engines.rag.modules import PromptResponseRagModule,␣
↪VectorStoreRetrievalRagModule
from griptape.engines.rag.stages import ResponseRagStage, RetrievalRagStage
from griptape.structures import Agent
from griptape.tasks import RagTask

#  Initialize Embedding Driver and Vector Store Driver

vector_store_driver = LocalVectorStoreDriver(embedding_driver=OpenAiEmbeddingDriver())

artifacts = [
    TextArtifact("Griptape builds AI-powered applications that connect securely to␣
↪your enterprise data and APIs."),
    TextArtifact("Griptape Agents provide incredible power and flexibility when␣
↪working with large language models."),
]
vector_store_driver.upsert_collection({"griptape": artifacts})

#  Instantiate the agent and add RagTask with the RagEngine

agent = Agent()
agent.add_task(
    RagTask(
        "Respond to the following query: {{ args[0] }}",
        rag_engine=RagEngine(
            retrieval_stage=RetrievalRagStage(
                retrieval_modules=[
                    VectorStoreRetrievalRagModule(
                        vector_store_driver=vector_store_driver, query_params={
↪"namespace": "griptape", "top_n": 20}
                    )
                ]
            ),
            response_stage=ResponseRagStage(
                response_modules=[PromptResponseRagModule(prompt_
↪driver=OpenAiChatPromptDriver(model="gpt-4.1"))]
            ),
        ),
    )
)
```

(continues on next page)

(continued from previous page)

```
#  Run the agent with a query string

agent.run("Give me information about Griptape")
```

Code Execution Task

To execute an arbitrary Python function, use the *CodeExecutionTask* . This task takes a python function, and authors can elect to return a custom artifact.

In this example, the `generate_title` function combines a hero's name and setting from previous tasks with a random title, returning a `TextArtifact` that contains the generated fantasy title. The output of this task can then be referenced by subsequent tasks using the `parent_outputs` templating variable, as shown in the final `PromptTask` .

```
import random

from griptape.artifacts import BaseArtifact, TextArtifact
from griptape.structures import Workflow
from griptape.tasks import CodeExecutionTask, PromptTask
from griptape.utils import StructureVisualizer

#  Define a function that will generate a fantasy title by combining inputs

def generate_title(task: CodeExecutionTask) -> BaseArtifact:
    # Make sure this is part of a valid structure
    structure = task.structure
    if structure is None:
        raise ValueError("Task must be part of a structure to run")

    # Retrieve outputs from previous tasks using their task IDs
    hero = structure.find_task("hero").output  # Gets the hero name from first prompt
    setting = structure.find_task("setting").output  # Gets the setting from second␣
↪prompt

    # List of epic titles to randomly choose from
    titles = ["the Brave", "the Shadow", "the Flame", "the Eternal", "the Cursed"]
    # Combine the hero name, random title, and setting into a full title
    generated_title = f"{hero} {random.choice(titles)} of {setting}"

    # Return the generated title as a TextArtifact that can be used by other tasks
    return TextArtifact(generated_title)

#  Create a new workflow to organize our tasks

workflow = Workflow()

#  Add a sequence of connected tasks to the workflow

workflow.add_tasks(
    # First task: Prompt for a hero name
    # The child_ids parameter connects this to the generate_title task
    PromptTask("Name a fantasy hero (e.g., Eldric)", id="hero", child_ids=["generate_
↪title"]),
```

(continues on next page)

(continued from previous page)

```
    # Second task: Prompt for a setting
    # Also connected to generate_title task
    PromptTask(
        "Describe a mystical setting in a couple sentences (e.g., the Shattered Isles)
↪",
        id="setting",
        child_ids=["generate_title"],
    ),
    # Third task: Execute our custom code to generate the title
    # The on_run parameter specifies which function to execute
    CodeExecutionTask(on_run=generate_title, id="generate_title", child_ids=["story
↪"]),
    # Fourth task: Prompt for a story using the generated title
    # {{ parent_outputs[generate_title] }} references the output from the previous␣
↪task
    PromptTask(
        "Write a brief, yet heroic tale about {{ parent_outputs[generate_title] }}. ",
        id="story",
    ),
)

#  Visualize the workflow structure (helpful for debugging)

print(StructureVisualizer(workflow).to_url())

#  Execute the entire workflow

workflow.run()
```

Branch Task

By default, a *Workflow* will only run a Task when all the Tasks it depends on have finished.

You can make use of *BranchTask* in order to tell the Workflow not to run all dependent tasks, but instead to pick and choose one or more paths to go down.

The `BranchTask` 's *python_runner* function can return one of three things:

1. An `InfoArtifact` containing the `id` of the Task to run next.
2. A `ListArtifact` of `InfoArtifact` s containing the `id` s of the Tasks to run next.
3. An *empty* `ListArtifact` to indicate that no Tasks should be run next.

```
from griptape.artifacts import InfoArtifact
from griptape.loaders import ImageLoader
from griptape.structures import Workflow
from griptape.tasks import BranchTask, PromptTask

def on_run(task: BranchTask) -> InfoArtifact:
    if "hot dog" in task.input.value:
        return InfoArtifact("hot_dog")
    return InfoArtifact("not_hot_dog")
```

(continues on next page)

(continued from previous page)

```
image_artifact = ImageLoader().load("tests/resources/mountain.png")

workflow = Workflow(
    tasks=[
        PromptTask(["What is in this image?", image_artifact], child_ids=["branch"]),
        BranchTask(
            "{{ parents_output_text }}",
            on_run=on_run,
            id="branch",
            child_ids=["hot_dog", "not_hot_dog"],
        ),
        PromptTask("Tell me about hot dogs", id="hot_dog"),
        PromptTask("Tell me about anything but hotdogs", id="not_hot_dog"),
    ]
)

workflow.run()
```

Image Generation Tasks

To generate an image, use one of the following add_tasks(*tasks) . All Image Generation Tasks accept an *Image Generation Drivers* .

All successful Image Generation Tasks will always output an *Image Artifact* . Each task can be configured to additionally write the generated image to disk by providing either the `output_file` or `output_dir` field. The `output_file` field supports file names in the current directory (`my_image.png`), relative directory prefixes (`images/my_image.png`), or absolute paths (`/usr/var/my_image.png`). By setting `output_dir` , the task will generate a file name and place the image in the requested directory.

Prompt Image Generation Task

The *Prompt Image Generation Task* generates an image from a text prompt.

```
from griptape.drivers.image_generation.openai import OpenAiImageGenerationDriver
from griptape.structures import Pipeline
from griptape.tasks import PromptImageGenerationTask

#  Create a driver configured to use OpenAIs DALL-E 3 model.

driver = OpenAiImageGenerationDriver(
    model="dall-e-3",
    quality="hd",
    style="natural",
)

#  Instantiate a pipeline.

pipeline = Pipeline()

#  Add a PromptImageGenerationTask to the pipeline.

pipeline.add_tasks(
```

(continues on next page)

(continued from previous page)

```
    PromptImageGenerationTask(
        input="{{ args[0] }}",
        image_generation_driver=driver,
        output_dir="images/",
    )
)

pipeline.run("An image of a mountain on a summer day")
```

Variation Image Generation Task

The *Variation Image Generation Task* generates an image using an input image and a text prompt. The input image is used as a basis for generating a new image as requested by the text prompt.

```
from griptape.drivers.image_generation.amazon_bedrock import␣
↪AmazonBedrockImageGenerationDriver
from griptape.drivers.image_generation_model.bedrock_stable_diffusion import (
    BedrockStableDiffusionImageGenerationModelDriver,
)
from griptape.loaders import ImageLoader
from griptape.structures import Pipeline
from griptape.tasks import VariationImageGenerationTask

#  Create a driver configured to use Stable Diffusion via Bedrock.

driver = AmazonBedrockImageGenerationDriver(
    image_generation_model_driver=BedrockStableDiffusionImageGenerationModelDriver(),
    model="stability.stable-diffusion-xl-v1",
)

#  Load input image artifact.

image_artifact = ImageLoader().load("tests/resources/mountain.png")

#  Instantiate a pipeline.

pipeline = Pipeline()

#  Add a VariationImageGenerationTask to the pipeline.

pipeline.add_task(
    VariationImageGenerationTask(
        input=("{{ args[0] }}", image_artifact),
        image_generation_driver=driver,
        output_dir="images/",
    )
)

pipeline.run("An image of a mountain landscape on a snowy winter day")
```

Inpainting Image Generation Task

The *Inpainting Image Generation Task* generates an image using an input image, a mask image, and a text prompt. The input image will be modified within the bounds of the mask image as requested by the text prompt.

```
from griptape.drivers.image_generation.amazon_bedrock import␣
↪AmazonBedrockImageGenerationDriver
from griptape.drivers.image_generation_model.bedrock_stable_diffusion import (
    BedrockStableDiffusionImageGenerationModelDriver,
)
from griptape.loaders import ImageLoader
from griptape.structures import Pipeline
from griptape.tasks import InpaintingImageGenerationTask

#  Create a driver configured to use Stable Diffusion via Bedrock.

driver = AmazonBedrockImageGenerationDriver(
    image_generation_model_driver=BedrockStableDiffusionImageGenerationModelDriver(),
    model="stability.stable-diffusion-xl-v1",
)

#  Load input image artifacts.

image_artifact = ImageLoader().load("tests/resources/mountain.png")

mask_artifact = ImageLoader().load("tests/resources/mountain-mask.png")

#  Instantiate a pipeline.

pipeline = Pipeline()

#  Add an InpaintingImageGenerationTask to the pipeline.

pipeline.add_task(
    InpaintingImageGenerationTask(
        input=("{{ args[0] }}", image_artifact, mask_artifact), image_generation_
↪driver=driver, output_dir="images/"
    )
)

pipeline.run("An image of a castle built into the side of a mountain")
```

Outpainting Image Generation Task

The *Outpainting Image Generation Task* generates an image using an input image, a mask image, and a text prompt. The input image will be modified outside the bounds of a mask image as requested by the text prompt.

```
from griptape.drivers.image_generation.amazon_bedrock import␣
↪AmazonBedrockImageGenerationDriver
from griptape.drivers.image_generation_model.bedrock_stable_diffusion import (
    BedrockStableDiffusionImageGenerationModelDriver,
)
from griptape.loaders import ImageLoader
```

(continues on next page)

(continued from previous page)

```
from griptape.structures import Pipeline
from griptape.tasks import OutpaintingImageGenerationTask

#  Create a driver configured to use Stable Diffusion via Bedrock.

driver = AmazonBedrockImageGenerationDriver(
    image_generation_model_driver=BedrockStableDiffusionImageGenerationModelDriver(),
    model="stability.stable-diffusion-xl-v1",
)

#  Load input image artifacts.

image_artifact = ImageLoader().load("tests/resources/mountain.png")

mask_artifact = ImageLoader().load("tests/resources/mountain-mask.png")

#  Instantiate a pipeline.

pipeline = Pipeline()

#  Add an OutpaintingImageGenerationTask to the pipeline.

pipeline.add_task(
    OutpaintingImageGenerationTask(
        input=("{{ args[0] }}", image_artifact, mask_artifact),
        image_generation_driver=driver,
        output_dir="images/",
    )
)

pipeline.run("An image of a mountain shrouded by clouds")
```

Structure Run Task

The *Structure Run Task* runs another Structure with a given input. This Task is useful for orchestrating multiple specialized Structures in a single run. Note that the input to the Task is a tuple of arguments that will be passed to the Structure.

```
import os

from griptape.drivers.structure_run.local import LocalStructureRunDriver
from griptape.drivers.web_search.google import GoogleWebSearchDriver
from griptape.rules import Rule, Ruleset
from griptape.structures import Agent, Pipeline
from griptape.tasks import StructureRunTask

team.run()
```

Assistant Task

The *Assistant Task* enables Structures to interact with various "assistant" services using *Assistant Drivers* .

```
import os

from griptape.drivers.assistant.griptape_cloud import GriptapeCloudAssistantDriver
from griptape.structures import Pipeline
from griptape.tasks import AssistantTask

pipeline = Pipeline(
    tasks=[
        AssistantTask(
            assistant_driver=GriptapeCloudAssistantDriver(
                assistant_id=os.environ["GT_CLOUD_ASSISTANT_ID"],
            ),
        ),
    ]
)

pipeline.run("Hello!")
```

Text to Speech Task

This Task enables Structures to synthesize speech from text using *Text to Speech Drivers* .

```
import os

from griptape.drivers.text_to_speech.elevenlabs import ElevenLabsTextToSpeechDriver
from griptape.structures import Pipeline
from griptape.tasks import TextToSpeechTask
```

(continues on next page)

(continued from previous page)

```
driver = ElevenLabsTextToSpeechDriver(
    api_key=os.environ["ELEVEN_LABS_API_KEY"],
    model="eleven_multilingual_v2",
    voice="Matilda",
)

task = TextToSpeechTask(
    text_to_speech_driver=driver,
)

Pipeline(tasks=[task]).run("Generate audio from this text: Hello, world!")
```

Audio Transcription Task

This Task enables Structures to transcribe speech from text using *Audio Transcription Drivers* .

```
from griptape.drivers.audio_transcription.openai import OpenAiAudioTranscriptionDriver
from griptape.loaders import AudioLoader
from griptape.structures import Pipeline
from griptape.tasks import AudioTranscriptionTask

driver = OpenAiAudioTranscriptionDriver(model="whisper-1")

task = AudioTranscriptionTask(
    input=lambda _: AudioLoader().load("tests/resources/sentences2.wav"),
    audio_transcription_driver=driver,
)

Pipeline(tasks=[task]).run()
```

Workflows

Overview

A *Workflow* is a non-sequential DAG that can be used for complex concurrent scenarios with tasks having multiple inputs.

You can access the final output of the Workflow by using the *Structured Output* attribute.

Context

Workflows have access to the following *RAG Context* variables in addition to the *base context* :

- `task_outputs` : dictionary containing mapping of all task IDs to their outputs.
- `parent_outputs` : dictionary containing mapping of parent task IDs to their outputs.
- `parents_output_text` : string containing the concatenated outputs of all parent tasks.
- `parents` : dictionary containing mapping of parent task IDs to their task objects.
- `children` : dictionary containing mapping of child task IDs to their task objects.

Workflow

Let's build a simple workflow. Let's say, we want to write a story in a fantasy world with some unique characters. We could setup a workflow that generates a world based on some keywords. Then we pass the world description to any number of child tasks that create characters. Finally, the last task pulls in information from all parent tasks and writes up a short story.

```
from griptape.structures import Workflow
from griptape.tasks import PromptTask
from griptape.utils import StructureVisualizer

world_task = PromptTask(
    "Create a fictional world based on the following key words {{ keywords|join(, ) }}
↪",
    context={"keywords": ["fantasy", "ocean", "tidal lock"]},
    id="world",
)

def character_task(task_id: str, character_name: str) -> PromptTask:
    return PromptTask(
        "Based on the following world description create a character named {{ name }}
↪:\n{{ parent_outputs[world] }}",
        context={"name": character_name},
        id=task_id,
        parent_ids=["world"],
    )

scotty_task = character_task("scotty", "Scotty")
annie_task = character_task("annie", "Annie")

story_task = PromptTask(
    "Based on the following description of the world and characters, write a short␣
↪story:\n{{ parent_outputs[world] }}\n{{ parent_outputs[scotty] }}\n{{ parent_
↪outputs[annie] }}",
    id="story",
    parent_ids=["world", "scotty", "annie"],
)

workflow = Workflow(tasks=[world_task, story_task, scotty_task, annie_task, story_
↪task])

print(StructureVisualizer(workflow).to_url())

workflow.run()
```

Note that we use the `StructureVisualizer` to get a visual representation of the workflow. If we visit the printed url, it should look like this:

Fig. 1: Workflow

Declarative vs Imperative Syntax

The above example showed how to create a workflow using the declarative syntax via the `parent_ids` init param, but there are a number of declarative and imperative options for you to choose between. There is no functional difference, they merely exist to allow you to structure your code as is most readable for your use case. Possibilities are illustrated below.

Declaratively specify parents (same as above example):

```
from griptape.rules import Rule
from griptape.structures import Workflow
from griptape.tasks import PromptTask

workflow = Workflow(
    tasks=[
        PromptTask("Name an animal", id="animal"),
        PromptTask("Describe {{ parent_outputs[animal] }} with an adjective", id=
↪"adjective", parent_ids=["animal"]),
        PromptTask("Name a {{ parent_outputs[adjective] }} animal", id="new-animal",␣
↪parent_ids=["adjective"]),
    ],
    rules=[Rule("output a single lowercase word")],
)

workflow.run()
```

Declaratively specify children:

```
from griptape.rules import Rule
from griptape.structures import Workflow
from griptape.tasks import PromptTask

workflow = Workflow(
    tasks=[
        PromptTask("Name an animal", id="animal", child_ids=["adjective"]),
        PromptTask(
            "Describe {{ parent_outputs[animal] }} with an adjective", id="adjective",
↪ child_ids=["new-animal"]
        ),
        PromptTask("Name a {{ parent_outputs[adjective] }} animal", id="new-animal"),
    ],
    rules=[Rule("output a single lowercase word")],
)

workflow.run()
```

Declaratively specifying a mix of parents and children:

```
from griptape.rules import Rule
from griptape.structures import Workflow
from griptape.tasks import PromptTask

workflow = Workflow(
    tasks=[
        PromptTask("Name an animal", id="animal"),
```

(continues on next page)

(continued from previous page)

```
        PromptTask(
            "Describe {{ parent_outputs[animal] }} with an adjective",
            id="adjective",
            parent_ids=["animal"],
            child_ids=["new-animal"],
        ),
        PromptTask("Name a {{ parent_outputs[adjective] }} animal", id="new-animal"),
    ],
    rules=[Rule("output a single lowercase word")],
)

workflow.run()
```

Imperatively specify parents:

```
from griptape.rules import Rule
from griptape.structures import Workflow
from griptape.tasks import PromptTask

animal_task = PromptTask("Name an animal", id="animal")
adjective_task = PromptTask("Describe {{ parent_outputs[animal] }} with an adjective",
↪ id="adjective")
new_animal_task = PromptTask("Name a {{ parent_outputs[adjective] }} animal", id="new-
↪animal")

adjective_task.add_parent(animal_task)
new_animal_task.add_parent(adjective_task)

workflow = Workflow(
    tasks=[animal_task, adjective_task, new_animal_task],
    rules=[Rule("output a single lowercase word")],
)

workflow.run()
```

Imperatively specify children:

```
from griptape.rules import Rule
from griptape.structures import Workflow
from griptape.tasks import PromptTask

animal_task = PromptTask("Name an animal", id="animal")
adjective_task = PromptTask("Describe {{ parent_outputs[animal] }} with an adjective",
↪ id="adjective")
new_animal_task = PromptTask("Name a {{ parent_outputs[adjective] }} animal", id="new-
↪animal")

animal_task.add_child(adjective_task)
adjective_task.add_child(new_animal_task)

workflow = Workflow(
    tasks=[animal_task, adjective_task, new_animal_task],
```

(continues on next page)

(continued from previous page)

```
    rules=[Rule("output a single lowercase word")],
)

workflow.run()
```

Imperatively specify a mix of parents and children:

```
from griptape.rules import Rule
from griptape.structures import Workflow
from griptape.tasks import PromptTask

workflow = Workflow(
    rules=[Rule("output a single lowercase word")],
)

animal_task = PromptTask("Name an animal", id="animal", structure=workflow)
adjective_task = PromptTask(
    "Describe {{ parent_outputs[animal] }} with an adjective", id="adjective",␣
↪structure=workflow
)
new_animal_task = PromptTask("Name a {{ parent_outputs[adjective] }} animal", id="new-
↪animal", structure=workflow)

adjective_task.add_parent(animal_task)
adjective_task.add_child(new_animal_task)

workflow.run()
```

Or even mix imperative and declarative:

```
from griptape.rules import Rule
from griptape.structures import Workflow
from griptape.tasks import PromptTask

animal_task = PromptTask("Name an animal", id="animal")
adjective_task = PromptTask(
    "Describe {{ parent_outputs[animal] }} with an adjective", id="adjective", parent_
↪ids=["animal"]
)

new_animal_task = PromptTask("Name a {{ parent_outputs[adjective] }} animal", id="new-
↪animal")
new_animal_task.add_parent(adjective_task)

workflow = Workflow(
    tasks=[animal_task, adjective_task, new_animal_task],
    rules=[Rule("output a single lowercase word")],
)

workflow.run()
```

Insert Parallel Tasks

`Workflow.insert_tasks()` provides a convenient way to insert parallel tasks between parents and children.

Imperatively insert parallel tasks between a parent and child:

```
from griptape.rules import Rule
from griptape.structures import Workflow
from griptape.tasks import PromptTask

workflow = Workflow(
    rules=[Rule("output a single lowercase word")],
)

animal_task = PromptTask("Name an animal", id="animal")
adjective_task = PromptTask("Describe {{ parent_outputs[animal] }} with an adjective",
↪ id="adjective")
color_task = PromptTask("Describe {{ parent_outputs[animal] }} with a color", id=
↪"color")
new_animal_task = PromptTask("Name an animal described as: \n{{ parents_output_text }}
↪", id="new-animal")

#  The following workflow runs animal_task, then (adjective_task, and color_task)

#  in parallel, then finally new_animal_task.

#
#  In other words, the output of animal_task is passed to both adjective_task and␣
↪color_task

#  and the outputs of adjective_task and color_task are then passed to new_animal_
↪task.

workflow.add_task(animal_task)
workflow.add_task(new_animal_task)
workflow.insert_tasks(animal_task, [adjective_task, color_task], new_animal_task)

workflow.run()
```

Bitshift Composition

Task relationships can also be set up with the Python bitshift operators `>>` and `<<` . The following statements are all functionally equivalent:

```
task1 >> task2
task1.add_child(task2)

task2 << task1
task2.add_parent(task1)

task3 >> [task4, task5]
task3.add_children([task4, task5])
```

When using the bitshift to compose operators, the relationship is set in the direction that the bitshift operator points. For example, `task1 >> task2` means that `task1` runs first and `task2` runs second. Multiple operators can be composed

– keep in mind the chain is executed left-to-right and the rightmost object is always returned. For example:

```
task1 >> task2 >> task3 << task4
```

is equivalent to:

```
task1.add_child(task2)
task2.add_child(task3)
task3.add_parent(task4)
```

11.7 Tools in Gen AI Builder

11.7.1 Overview

One of the most powerful features of Gen AI Builder is the ability to use tools that interact with the outside world. Tools give the LLM abilities to invoke APIs, reference data sets, and expand their capabilities beyond simple text generation.

Many of our *Prompt Drivers* leverage the native function calling built into LLMs. For models that do not support this, Gen AI Builder provides its own implementation using the ReAct technique.

You can switch between these strategies by setting `use_native_tools` to `True` (LLM-native tool calling) or `False` (Gen AI Builder tool calling) on your *Prompt Drivers* .

11.7.2 Custom Tools

See *Custom Tools* for more information on building your own tools.

11.7.3 Tool Output and Task Memory

Output artifacts from all tool activities (except `InfoArtifact` and `ErrorArtifact`) are stored in short-term `TaskMemory` . To disable this behavior, set the `off_prompt` tool parameter to `False` .

11.7.4 Using Tools in Pipelines

Gen AI Builder provides a set of official tools for accessing and processing data. You can also *build your own tools* .

Here is an example of a Pipeline using tools:

```
from griptape.structures import Pipeline
from griptape.tasks import PromptTask
from griptape.tools import FileManagerTool, PromptSummaryTool, WebScraperTool

pipeline = Pipeline()

pipeline.add_tasks(
    PromptTask(
        "Load https://www.griptape.ai, summarize it, and store it in a file called␣
↪griptape.txt",
        tools=[
            WebScraperTool(off_prompt=True),
            FileManagerTool(off_prompt=True),
            PromptSummaryTool(off_prompt=False),
        ],
    ),
```

(continues on next page)

(continued from previous page)

```
)

pipeline.run()
```

Custom Tools

Overview

Building your own tools is easy with Gen AI Builder!

Tools are nothing more than Python classes that inherit from *BaseTool* . Each method in the class is decorated with an *process_output(tool_activity, subtask, output_artifact)* decorator which informs the LLM how and when it should use that Tool Activity.

Random Tool

Here is a simple Tool for performing various operations with the `random` module.

```
import random

from schema import Literal, Optional, Schema

from griptape.artifacts import TextArtifact
from griptape.artifacts.list_artifact import ListArtifact
from griptape.structures import Agent
from griptape.tools import BaseTool
from griptape.utils.decorators import activity

class RandomTool(BaseTool):
    @activity(
        config={
            "description": "Can be used to generate random numbers",
        }
    )
    def generate_rand_num(self) -> TextArtifact:
        """Generate a random number between 0 and 1.

        Returns:
            TextArtifact: The random number as a Text Artifact.
        """
        return TextArtifact(random.random())

    @activity(
        config={
            "description": "Can be used to generate random numbers",
            "schema": Schema(
                {
                    Literal("start", description="The start of the rand range,␣
↪inclusive."): int,
                    Literal("stop", description="The start of the rand range,␣
↪exclusive."): int,
                }
            ),
```

(continues on next page)

(continued from previous page)

```
        }
    )
    def generate_rand_range(self, start: int, stop: int) -> TextArtifact:
        """Generate a random number between start and stop.

        Args:
            start (int): The starting number.
            stop (int): The ending number.

        Returns:
            TextArtifact: The random number as a Text Artifact.
        """
        return TextArtifact(random.randrange(start, stop))

    @activity(
        config={
            "description": "Can be used to select a random item from a list",
            "schema": Schema(
                {
                    "items": [str],
                }
            ),
        }
    )
    def select_rand_item(self, *, values: dict) -> TextArtifact:
        """Select a random item from a list.

        Args:
            values (dict): The values declared by the schema.

        Returns:
            TextArtifact: The selected item as a Text Artifact.
        """
        items = values["items"]

        return TextArtifact(random.choice(items))

    @activity(
        config={
            "description": "Can be used to sample a list",
            "schema": Schema(
                {
                    "items": [str],
                    Optional("k"): int,
                }
            ),
        }
    )
    def sample_list(self, *, params: dict) -> ListArtifact[TextArtifact]:
        """Shuffle a list.

        Args:
```

(continues on next page)

(continued from previous page)

```
            params (dict): A dictionary containing a key, `values`, which contains␣
↪the values declared by the schema.

        Returns:
            TextArtifact: The sampled list as a List Artifact of Text Artifacts.
        """
        values = params["values"]

        items = values["items"]
        k = values.get("k", 5)

        sampled = random.sample(items, k)

        return ListArtifact([TextArtifact(item) for item in sampled])

agent = Agent(tools=[RandomTool()])

agent.run("Generate a number between 5 and 10, then generate that many animals,␣
↪sample 3, then randomly select one.")
```

Tool Activities

Activities are actions an LLM can perform with a various Tool. They pair a natural language description with some code to execute. Some examples:

- "Can be used to create a random number" -> `generate_rand_num`
- "Can be used to select a random item from a list" -> `select_rand_item`

Technically, each Activity is a method in the tool class that's decorated with the *process_output(tool_activity, subtask, output_artifact)* decorator.

Gen AI Builder will convert the Tool and its Activities into the appropriate format for the LLM to use. You can see the schema for a particular Activity by calling *to_json_schema* .

```
from rich.pretty import pprint

from griptape.tools import CalculatorTool

tool = CalculatorTool()

pprint(tool.to_activity_json_schema(tool.calculate, "Calculate Schema"))
```

Each Activity takes a `config` keyword argument that contains the configuration for the Activity. The configuration can contain:

- `description` (str): A plain text description of the Activity. Ensure that the description is clear and concise as it will help inform the LLM of when to pick this Activity.
- `schema` (optional): An optional instance of `Schema` that defines the input values to the Activity. This field should be omitted if the Activity does not accept any input values.

Activity Methods

Activity decorated methods should return an *Artifacts* , though Gen AI Builder will automatically convert any other return type to an *InfoArtifact* .

If an Activity's config declares a `schema` , the method should declare parameters using one of the following styles:

- Standard python keyword arguments. See `generate_random_number` .
- `values` (dict): A dictionary of the input values to the Activity. See `select_random_item` .
- `params` (dict): A dictionary that will contain a single key, `values` . See `sample_list` . Other keys may be added in the future, though generally, you should prefer using one of the other styles.

Warning

Do not name any schema fields as *values* or *params* . They are reserved for the Activity method signature.

Tool Dependencies

Each Tool can also have its own dependencies. You can specify them in a `requirements.txt` file in the tool directory and Gen AI Builder will install them during Tool execution. To start, create a directory for your Tool inside your project. The directory must have the following structure:

```
griptape/tools/calculator/
├── __init__.py
├── requirements.txt # file with tool Python dependencies
└── tool.py # file with tool Python class
```

That's it! Import and use your Tool in your project as you would with any other Gen AI Builder Tool.

Check out other *Gen AI Builder Tools* to learn more about tool implementation details.

Official Tools

Overview

Gen AI Builder provides a set of official Tools for common tasks. In general, Gen AI Builder-included Tools are designed to be general-purpose and Driver-based for easy integration with different backends.

Tools

Audio Transcription

This Tool enables *Agents* to transcribe speech from text using *Audio Transcription Drivers* .

```
from griptape.drivers.audio_transcription.openai import OpenAiAudioTranscriptionDriver
from griptape.structures import Agent
from griptape.tools.audio_transcription.tool import AudioTranscriptionTool

driver = OpenAiAudioTranscriptionDriver(model="whisper-1")

tool = AudioTranscriptionTool(
    off_prompt=False,
    audio_transcription_driver=driver,
```

(continues on next page)

(continued from previous page)

```
)

Agent(tools=[tool]).run(
    "Transcribe the following audio file: /Users/andrew/code/griptape/tests/resources/
↪sentences2.wav"
)
```

Calculator

This tool enables LLMs to make simple calculations.

```
from griptape.structures import Agent
from griptape.tools import CalculatorTool

#  Create an agent with the CalculatorTool tool

agent = Agent(tools=[CalculatorTool()])

#  Run the agent with a task to perform the arithmetic calculation of \(10^5\)

agent.run("What is 10 raised to the power of 5?")
```

Computer

This tool enables LLMs to execute Python code and run shell commands inside a Docker container. You have to have the Docker daemon running in order for this tool to work.

You can specify a local working directory and environment variables during tool initialization:

```
from griptape.structures import Agent
from griptape.tools import ComputerTool

#  Initialize the ComputerTool tool

computer = ComputerTool()

#  Create an agent with the ComputerTool tool

agent = Agent(tools=[computer])

agent.run("Make 2 files and then list the files in the current directory")
```

Date Time

This tool enables LLMs to get current date and time.

```
from griptape.structures import Agent
from griptape.tools import DateTimeTool

agent = Agent(tools=[DateTimeTool()])

agent.run("What day is 5 days past christmas in 2026?")
```

Email

The *EmailTool* enables LLMs to send emails.

```
import os

from griptape.tools import EmailTool

email_tool = EmailTool(
    smtp_host=os.environ.get("SMTP_HOST"),
    smtp_port=int(os.environ.get("SMTP_PORT", "465")),
    smtp_password=os.environ.get("SMTP_PASSWORD"),
    smtp_user=os.environ.get("FROM_EMAIL"),
    smtp_use_ssl=bool(os.environ.get("SMTP_USE_SSL")),
)
```

For debugging purposes, you can run a local SMTP server that the LLM can send emails to:

```
python -m smtpd -c DebuggingServer -n localhost:1025
```

Extraction

The *ExractionTool* enables LLMs to extract structured text from unstructured data.

```
import schema

from griptape.engines import JsonExtractionEngine
from griptape.structures import Agent
from griptape.tools import ExtractionTool, WebScraperTool

agent = Agent(
    input="Load {{ args[0] }} and extract key info",
    tools=[
        WebScraperTool(off_prompt=True),
        ExtractionTool(
            off_prompt=False,
            extraction_engine=JsonExtractionEngine(
                template_schema=schema.Schema(
                    {
                        "company_name": str,
                        "industry": str,
                        schema.Literal(
                            "product_features",
                            description="List of key product features.",
                        ): list[str],
                    }
                ).json_schema("Company Info"),
            ),
        ),
    ],
)
agent.run("https://griptape.ai")
```

File Manager

This tool enables LLMs to save and load files.

```
from pathlib import Path

from griptape.structures import Agent
from griptape.tools import FileManagerTool

#  Initialize the FileManagerTool tool with the current directory as its base

file_manager_tool = FileManagerTool()

#  Add the tool to the Agent

agent = Agent(tools=[file_manager_tool])

#  Directly create a file named sample1.txt with some content

filename = "sample1.txt"
content = "This is the content of sample1.txt"

Path(filename).write_text(content)

#  Now, read content from the file sample1.txt using the agents command

agent.run("Can you get me the sample1.txt file?")
```

`

Gen AI Builder Tool

The *GriptapeCloudToolTool* integrates with Gen AI Builder's hosted Tools.

Note: This tool requires a Tool hosted in Gen AI Builder and an API Key for access.

```
import os

from griptape.structures import Agent
from griptape.tools.griptape_cloud_tool.tool import GriptapeCloudToolTool

agent = Agent(
    tools=[
        GriptapeCloudToolTool(  # Tool is configured as a random number generator
            tool_id=os.environ["GT_CLOUD_TOOL_ID"],
        )
    ]
)
agent.run("Generate a number between 1 and 10")
```

Image Query

This tool allows Agents to execute natural language queries on the contents of images using multimodal models.

```
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.structures import Agent
from griptape.tools import ImageQueryTool

driver = OpenAiChatPromptDriver(model="gpt-4.1")

#  Create an Image Query Tool configured to use the engine.

tool = ImageQueryTool(
    prompt_driver=driver,
)

#  Create an agent and provide the tool to it.

Agent(tools=[tool]).run("Describe the weather in the image tests/resources/mountain.
↪png in one word.")
```

Inpainting Image Generation

This tool allows LLMs to generate images using inpainting, where an input image is altered within the area specified by a mask image according to a prompt. The input and mask images can be provided either by their file path or by their *Task Memory and Off Prompt* references.

```
from griptape.drivers.image_generation.amazon_bedrock import␣
↪AmazonBedrockImageGenerationDriver
from griptape.drivers.image_generation_model.bedrock_stable_diffusion import (
    BedrockStableDiffusionImageGenerationModelDriver,
)
from griptape.structures import Agent
from griptape.tools import InpaintingImageGenerationTool

#  Create a driver configured to use Stable Diffusion via Bedrock.

driver = AmazonBedrockImageGenerationDriver(
    image_generation_model_driver=BedrockStableDiffusionImageGenerationModelDriver(),
    model="stability.stable-diffusion-xl-v1",
)

#  Create a tool configured to use the engine.

tool = InpaintingImageGenerationTool(
    image_generation_driver=driver,
)

#  Create an agent and provide the tool to it.

Agent(tools=[tool]).run(
    "Generate an image of a castle built into the side of a mountain by inpainting␣
↪the "
```

(continues on next page)

(continued from previous page)

```
    "image at tests/resources/mountain.png using the mask at tests/resources/mountain-
↪mask.png."
)
```

Outpainting Image Generation

This tool allows LLMs to generate images using outpainting, where an input image is altered outside of the area specified by a mask image according to a prompt. The input and mask images can be provided either by their file path or by their *Task Memory and Off Prompt* references.

```
from griptape.drivers.image_generation.amazon_bedrock import␣
↪AmazonBedrockImageGenerationDriver
from griptape.drivers.image_generation_model.bedrock_stable_diffusion import (
    BedrockStableDiffusionImageGenerationModelDriver,
)
from griptape.structures import Agent
from griptape.tools import OutpaintingImageGenerationTool

#  Create a driver configured to use Stable Diffusion via Bedrock.

driver = AmazonBedrockImageGenerationDriver(
    image_generation_model_driver=BedrockStableDiffusionImageGenerationModelDriver(),
    model="stability.stable-diffusion-xl-v1",
)

#  Create a tool configured to use the engine.

tool = OutpaintingImageGenerationTool(
    image_generation_driver=driver,
)

#  Create an agent and provide the tool to it.

Agent(tools=[tool]).run(
    "Generate an image of a mountain shrouded by clouds by outpainting the "
    "image at tests/resources/mountain.png using the mask at tests/resources/mountain-
↪mask.png."
)
```

Prompt Image Generation

This tool allows LLMs to generate images from a text prompt.

```
from griptape.drivers.image_generation.amazon_bedrock import␣
↪AmazonBedrockImageGenerationDriver
from griptape.drivers.image_generation_model.bedrock_stable_diffusion import (
    BedrockStableDiffusionImageGenerationModelDriver,
)
from griptape.structures import Agent
from griptape.tools import PromptImageGenerationTool
```

(continues on next page)

(continued from previous page)

```
#  Create a driver configured to use Stable Diffusion via Bedrock.

driver = AmazonBedrockImageGenerationDriver(
    image_generation_model_driver=BedrockStableDiffusionImageGenerationModelDriver(),
    model="stability.stable-diffusion-xl-v1",
)

#  Create a tool configured to use the engine.

tool = PromptImageGenerationTool(
    image_generation_driver=driver,
)

#  Create an agent and provide the tool to it.

Agent(tools=[tool]).run("Generate an image of a mountain on a summer day.")
```

Prompt Summary

The *PromptSummaryTool* enables LLMs summarize text data.

```
from griptape.structures import Agent
from griptape.tools import PromptSummaryTool, WebScraperTool

agent = Agent(tools=[WebScraperTool(off_prompt=True), PromptSummaryTool()])

agent.run(
    "How can I build Neovim from source for MacOS according to this https://github.
↪com/neovim/neovim/blob/master/BUILD.md"
)
```

`

Rag

The *RagTool* enables LLMs to query modular RAG engines.

Here is an example of how it can be used with a local vector store driver:

```
from griptape.artifacts import TextArtifact
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.drivers.vector.local import LocalVectorStoreDriver
from griptape.engines.rag import RagEngine
from griptape.engines.rag.modules import PromptResponseRagModule,␣
↪VectorStoreRetrievalRagModule
from griptape.engines.rag.stages import ResponseRagStage, RetrievalRagStage
from griptape.structures import Agent
from griptape.tools import RagTool

vector_store_driver = LocalVectorStoreDriver(embedding_driver=OpenAiEmbeddingDriver())
```

(continues on next page)

(continued from previous page)

```
artifact = TextArtifact(
    "Griptape builds AI-powered applications that connect securely to your enterprise␣
↪data and APIs."
    "Griptape Agents provide incredible power and flexibility when working with large␣
↪language models."
)

vector_store_driver.upsert(artifact, namespace="griptape")

rag_tool = RagTool(
    description="Contains information about Griptape",
    off_prompt=False,
    rag_engine=RagEngine(
        retrieval_stage=RetrievalRagStage(
            retrieval_modules=[
                VectorStoreRetrievalRagModule(
                    vector_store_driver=vector_store_driver, query_params={"namespace
↪": "griptape", "top_n": 20}
                )
            ]
        ),
        response_stage=ResponseRagStage(
            response_modules=[PromptResponseRagModule(prompt_
↪driver=OpenAiChatPromptDriver(model="gpt-4.1"))]
        ),
    ),
)

agent = Agent(tools=[rag_tool])

agent.run("what is Griptape?")
```

Query

The *ImageQueryTool* enables Agents to query unstructured data for specific information.

```
from griptape.structures import Agent
from griptape.tools import QueryTool, WebScraperTool

agent = Agent(tools=[WebScraperTool(off_prompt=True), QueryTool()])

agent.run("Tell me about the architecture as described here: https://neovim.io/doc/
↪user/vim_diff.html")
```

Rest Api

This tool enables LLMs to call REST APIs.

The *RestApiTool* tool uses the following parameters:

The following example is built using https://jsonplaceholder.typicode.com/guide/.

My First Post, A Journey.,

This tool enables LLMs to execute SQL statements via SQLAlchemy . Depending on your underlying SQL engine, configure your `engine_url` and give the LLM a hint about what engine you are using via `engine_name` , so that it can create engine-specific statements.

```
import os

import boto3

from griptape.drivers.sql.amazon_redshift import AmazonRedshiftSqlDriver
from griptape.loaders import SqlLoader
from griptape.structures import Agent
from griptape.tools import SqlTool

session = boto3.Session()

sql_loader = SqlLoader(
    sql_driver=AmazonRedshiftSqlDriver(
        database=os.environ["REDSHIFT_DATABASE"],
        session=session,
        cluster_identifier=os.environ["REDSHIFT_CLUSTER_IDENTIFIER"],
    )
)

sql_tool = SqlTool(
    sql_loader=sql_loader,
    table_name="people",
    table_description="contains information about tech industry professionals",
    engine_name="redshift",
)

agent = Agent(tools=[sql_tool])
agent.run("SELECT * FROM people;")
```

The *StructureRunTool* Tool provides a way to run Structures via a Tool. It requires you to provide a *Structure Run Drivers* to run the Structure in the desired environment.

```
import os

from griptape.drivers.structure_run.griptape_cloud import␣
↪GriptapeCloudStructureRunDriver
from griptape.structures import Agent
from griptape.tools import StructureRunTool

base_url = os.environ["GT_CLOUD_BASE_URL"]
api_key = os.environ["GT_CLOUD_API_KEY"]
structure_id = os.environ["GT_CLOUD_STRUCTURE_ID"]

structure_run_tool = StructureRunTool(
    description="RAG Expert Agent - Structure to invoke with natural language queries␣
↪about the topic of Retrieval Augmented Generation",
    structure_run_driver=GriptapeCloudStructureRunDriver(
        base_url=base_url,
```

(continues on next page)

(continued from previous page)

```
        api_key=api_key,
        structure_id=structure_id,
    ),
)

#  Set up an agent using the StructureRunTool tool

agent = Agent(tools=[structure_run_tool])

#  Task: Ask the Griptape Cloud Hosted Structure about modular RAG

agent.run("what is modular RAG?")
```

This Tool enables LLMs to synthesize speech from text using *Text to Speech Drivers* .

```
import os

from griptape.drivers.text_to_speech.elevenlabs import ElevenLabsTextToSpeechDriver
from griptape.structures import Agent
from griptape.tools.text_to_speech.tool import TextToSpeechTool

driver = ElevenLabsTextToSpeechDriver(
    api_key=os.environ["ELEVEN_LABS_API_KEY"],
    model="eleven_multilingual_v2",
    voice="Matilda",
)

tool = TextToSpeechTool(
    text_to_speech_driver=driver,
)

Agent(tools=[tool]).run("Generate audio from this text: Hello, world!")
```

This Tool allows LLMs to generate variations of an input image from a text prompt. The input image can be provided either by its file path or by its *Task Memory and Off Prompt* reference.

```
from griptape.drivers.image_generation.amazon_bedrock import␣
↪AmazonBedrockImageGenerationDriver
from griptape.drivers.image_generation_model.bedrock_stable_diffusion import (
    BedrockStableDiffusionImageGenerationModelDriver,
)
from griptape.structures import Agent
from griptape.tools import VariationImageGenerationTool

#  Create a driver configured to use Stable Diffusion via Bedrock.

driver = AmazonBedrockImageGenerationDriver(
    image_generation_model_driver=BedrockStableDiffusionImageGenerationModelDriver(
        style_preset="pixel-art",
    ),
    model="stability.stable-diffusion-xl-v1",
)
```

(continues on next page)

(continued from previous page)

```
#  Create a tool configured to use the engine.

tool = VariationImageGenerationTool(
    image_generation_driver=driver,
)

#  Create an agent and provide the tool to it.

Agent(tools=[tool]).run(
    "Generate a variation of the image located at tests/resources/mountain.png␣
↪depicting a mountain on a winter day"
)
```

```
from griptape.drivers.image_generation.amazon_bedrock import␣
↪AmazonBedrockImageGenerationDriver
from griptape.drivers.image_generation_model.bedrock_stable_diffusion import (
    BedrockStableDiffusionImageGenerationModelDriver,
)
from griptape.structures import Agent
from griptape.tools import FileManagerTool, PromptImageGenerationTool,␣
↪VariationImageGenerationTool

#  Create a driver configured to use Stable Diffusion via Bedrock.

driver = AmazonBedrockImageGenerationDriver(
    image_generation_model_driver=BedrockStableDiffusionImageGenerationModelDriver(
        style_preset="pixel-art",
    ),
    model="stability.stable-diffusion-xl-v1",
)

#  Create a prompt image generation client configured to use the driver.

prompt_tool = PromptImageGenerationTool(image_generation_driver=driver, off_
↪prompt=True)

#  Create a variation image generation client configured to use the driver.

variation_tool = VariationImageGenerationTool(
    image_generation_driver=driver,
    off_prompt=True,
)

file_tool = FileManagerTool()

#  Create an agent and provide the tools to it.

agent = Agent(tools=[prompt_tool, variation_tool, file_tool])

#  Run the agent using a prompt motivating it to generate an image, then
```

(continues on next page)

(continued from previous page)

```
#  create a variation of the image present in task memory.

agent.run(
    "Generate an image of a mountain on a summer day. Then, generate a "
    "variation of this image depicting the same mountain scene on a winter day."
    "Save them images to disk and return the file paths. "
)
```

The *VectorStoreTool* enables LLMs to query vector stores.

Here is an example of how it can be used with a local vector store driver:

```
from griptape.chunkers import TextChunker
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver
from griptape.drivers.vector.local import LocalVectorStoreDriver
from griptape.loaders import WebLoader
from griptape.structures import Agent
from griptape.tools import VectorStoreTool

NAMESPACE = "griptape"

vector_store_driver = LocalVectorStoreDriver(
    embedding_driver=OpenAiEmbeddingDriver(),
)

artifacts = WebLoader().load("https://www.griptape.ai")
chunks = TextChunker().chunk(artifacts)

vector_store_driver.upsert_collection({NAMESPACE: chunks})
vector_db = VectorStoreTool(
    description="This DB has information about the Griptape Python framework",
    vector_store_driver=vector_store_driver,
    query_params={"namespace": NAMESPACE},
)

agent = Agent(tools=[vector_db])

agent.run("what is Griptape?")
```

This tool enables LLMs to scrape web pages for full text, summaries, authors, titles, and keywords. It can also execute search queries to answer specific questions about the page. This tool uses OpenAI APIs for some of its activities, so in order to use it provide a valid API key in `openai_api_key` .

```
from griptape.structures import Agent
from griptape.tools import PromptSummaryTool, WebScraperTool

agent = Agent(tools=[WebScraperTool(off_prompt=True), PromptSummaryTool(off_
↪prompt=False)])

agent.run("Based on https://www.griptape.ai/, tell me what griptape is")
```

This tool enables LLMs to search the web.

```
import os

from griptape.drivers.web_search.google import GoogleWebSearchDriver
from griptape.structures import Agent
from griptape.tools import WebSearchTool

#  Initialize the WebSearchTool tool with necessary parameters

web_search_tool = WebSearchTool(
    web_search_driver=GoogleWebSearchDriver(
        api_key=os.environ["GOOGLE_API_KEY"],
        search_id=os.environ["GOOGLE_API_SEARCH_ID"],
        results_count=5,
        language="en",
        country="us",
    ),
)

#  Set up an agent using the WebSearchTool tool

agent = Agent(tools=[web_search_tool])

#  Task: Search the web for a specific query

agent.run("Tell me how photosynthesis works")
```

Extra schema properties can be added to the Tool to allow for more customization if the Driver supports it. In this example, we add a `sort` property to the `search` Activity which will be added as a *Google custom search query parameter* .

```
import os

import schema

from griptape.drivers.web_search.google import GoogleWebSearchDriver
from griptape.structures import Agent
from griptape.tools import WebSearchTool

agent = Agent(
    tools=[
        WebSearchTool(
            web_search_driver=GoogleWebSearchDriver(
                api_key=os.environ["GOOGLE_API_KEY"],
                search_id=os.environ["GOOGLE_API_SEARCH_ID"],
            ),
            extra_schema_properties={
                "search": {
                    schema.Literal(
                        "sort",
                        description="Date range to search within. Format:␣
↪date:r:YYYYMMDD:YYYYMMDD",
                    ): str
                }
```

(continues on next page)

(continued from previous page)

```
            },
        )
    ],
)

agent.run("Search for articles about the history of the internet from 1990 to 2000")
```
