Gen AI Builder SDK

Release 1.3

EnterpriseDB Corporation

Oct 31, 2025

Contents

1 Why Consider a Framework? 2

2 Prerequisites 3
- 2.1 1. OpenAI API Key . . . 3
- 2.2 2. Install Gen AI Builder . . . 3
- 2.3 Using Uv . . . 3
- 2.4 Using Pip . . . 4
- 2.5 Installing Optional Dependencies . . . 4

3 Prompt Task 5

4 Changing Models 6

5 Templating 7

6 Rules 8

7 Structured Output 11

8 Conversation Memory 13

9 Tools 15

10 Structures 17
- 10.1 Directly Using PromptSummaryEngine . . . 18
- 10.2 TextSummaryTask . . . 20

11 Conclusion and Next Steps 23
- 11.1 Data abstractions . . . 23
  - 11.1.1 Overview . . . 23
    - Artifacts . . . 24
    - Chunkers . . . 25
    - Loaders . . . 26
- 11.2 Prompt . . . 29
  - 11.2.1 Overview . . . 29
  - 11.2.2 Structured Output . . . 30
    - Prompt Task . . . 31
  - 11.2.3 Prompt Drivers . . . 32

OpenAI Chat . . . 32
OpenAI Compatible . . . 33
Azure OpenAI Chat . . . 34
Gen AI Builder . . . 34
Cohere . . . 35
Anthropic . . . 35
Google . . . 36
Amazon Bedrock . . . 36
Ollama . . . 37
Hugging Face Hub . . . 37
Text Generation Interface . . . 38
Hugging Face Pipeline . . . 38
Amazon SageMaker Jumpstart . . . 39
Grok . . . 39
Perplexity . . . 39
11.3 RAG Engine . . . 85
11.3.1 RAG Engines . . . 85
RAG Stages . . . 86
RAG Modules . . . 86
Query Stage . . . 86
Query Stage Modules . . . 86
Retrieval Stage . . . 86
Retrieval Stage Modules . . . 86
Response Stage . . . 86
Response Stage Modules . . . 86
RAG Context . . . 86
Simple Example . . . 86
Advanced Example . . . 87
RAG Tool . . . 90
11.4 Events . . . 93
11.4.1 Overview . . . 93
11.4.2 Specific Event Types . . . 93
11.4.3 All Event Types . . . 94
11.4.4 Stream Iterator . . . 95
11.4.5 Context Managers . . . 95
11.4.6 Streaming . . . 95
11.4.7 Counting Tokens . . . 98
11.4.8 Inspecting Payloads . . . 98
11.4.9 `EventListenerDriver.on_event` Return Value Behavior . . . 98
`EventListener.on_event` is None . . . 98
Return `BaseEvent` or `dict` . . . 98
Return `None` . . . 98
11.5 SDK reference . . . 102
11.5.1 artifacts . . . 102
Attributes . . . 102
to_text() . . . 103
Attributes . . . 103

Gen AI Builder is a Python framework designed to simplify the development of generative AI applications. It offers a set of straightforward, flexible abstractions for working with areas such as Large Language Models (LLMs), Retrieval-Augmented Generation (RAG), and much more.

1. **Technology-agnostic**: Gen AI Builder is designed to work with any capable LLM, data store, and backend through the abstraction of Drivers.
2. **Minimal prompt engineering**: It's much easier to reason about code written in Python, not natural languages. Gen AI Builder aims to default to Python in most cases unless absolutely necessary.

CHAPTER 1

Why Consider a Framework?

If you're just beginning to experiment with generative AI, it's often best to start by building simple applications from scratch. However, as your project grows in complexity, a framework like Gen AI Builder can provide structure and best practices that help you maintain clarity and scalability.

Gen AI Builder strives to be transparent about the underlying AI techniques it uses. Nevertheless, having some foundational knowledge of LLMs and related technology will be helpful when building more sophisticated applications.

CHAPTER 2

Prerequisites

2.1 1. OpenAI API Key

By default, Gen AI Builder uses OpenAI for LLM interactions. We'll learn how to change this via *Prompt Drivers* later. For now:

1. Obtain an OpenAI API key .
2. Set it as an environment variable:

```
export OPENAI_API_KEY="your-api-key"
```

Prompt Drivers are model agnostic, letting you switch out LLM providers without changing application code.

> **Tip**
>
> To securely and easily manage environment variables, check out tools like python-dotenv or mise .

2.2 2. Install Gen AI Builder

Gen AI Builder can be installed via multiple methods. Below are two popular approaches:

2.3 Using Uv

uv is a fast, user-friendly dependency manager. If you've used poetry , `uv` is a similar project but with a focus on simplicity and speed.

1. *Install `uv* <https://docs.astral.sh/uv/getting-started/installation/>`_ .
2. Initialize a new project:

```
uv init griptape-quickstart
```

3. Change into the new directory:

```
cd griptape-quickstart
```

4. Add Gen AI Builder as a dependency:

```
uv add "griptape[all]"
```

5. A virtual environment will be automatically created. Activate it:

```
source .venv/bin/activate
```

> **Note**
>
> If you use another shell (like *fish*), this command may differ.

> **Tip**
>
> If you're using mise , you can configure it to automatically activate your virtual environment .

2.4 Using Pip

If `uv` isn't your style, you can always install Gen AI Builder using `pip` :

```
pip install "griptape[all]" -U
```

2.5 Installing Optional Dependencies

Gen AI Builder provides optional dependencies that enable specific features and third-party integrations. If you're new to Gen AI Builder, consider installing `[all]` to unlock its full functionality. This ensures you have everything you need right from the start.

However, for a more streamlined setup or if you only need certain features, you have two primary options:

1. **Core Dependencies**: These provide the minimal, foundational set of libraries for Gen AI Builder to run most default features.
2. **Optional Dependencies**: These are additional, vendor-specific drivers (e.g., for Anthropic or Pinecone). Any driver requiring an extra will indicate this in the documentation.

For a core-only installation:

```
uv add griptape
```

To install specific optional dependencies such as Anthropic and Pinecone drivers—use:

```
uv add "griptape[drivers-prompt-anthropic,drivers-vector-pinecone]"
```

To see all available optional dependencies, see Gen AI Builder's pyproject.toml .

CHAPTER 3

Prompt Task

With everything set up, let's start building! One of Gen AI Builder's core abstractions is a *Prompt Task* . We'll start with a *Prompt Task* to prompt the LLM with some text.

Create a file named `app.py` and add:

```
from griptape.tasks import PromptTask

task = PromptTask()

output = task.run("Hello there!")

print(output)
```

Then run:

```
python app.py
```

> **Tip**
>
> Whenever you see a "Logs" tab in the Gen AI Builder documentation, you can click it to view logs and outputs.

If you got a response from the model, congrats! You've created your first generative AI application with Gen AI Builder. This introductory guide sticks to the *Prompt Task* , but Gen AI Builder supports a wide range of add_tasks(*tasks) . Explore them to see what else you can do.

CHAPTER 4

Changing Models

Gen AI Builder's "Prompt Drivers" make switching model providers simple. For instance, to use Anthropic , follow the same steps you used for the OpenAI key, but this time set an *Anthropic API key* :

```
export ANTHROPIC_API_KEY="your-api-key"
```

Then import *Anthropic Prompt Driver* and pass it to your Task:

```
from griptape.drivers.prompt.anthropic import AnthropicPromptDriver
from griptape.tasks import PromptTask

task = PromptTask(prompt_driver=AnthropicPromptDriver(model="claude-3-7-sonnet-latest
↪"))

task.run("Hello there!")
```

Run the script again to see a similar output. Notice you didn't have to change any of the application-level logic; you only changed the driver.

For the remainder of this guide, we'll revert to the *OpenAI Chat Prompt Driver* :

```
from griptape.drivers.prompt.openai_chat_prompt_driver import OpenAiChatPromptDriver
from griptape.tasks import PromptTask

task = PromptTask(prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1"))

task.run("Hello there!")
```

If you'd like to keep using Anthropic, be sure to adjust code accordingly.

CHAPTER 5

Templating

Gen AI Builder uses the popular Jinja templating engine to help create dynamic prompts. Let's adapt our Prompt Task to utilize a Jinja template:

```
from griptape.drivers.prompt.openai_chat_prompt_driver import OpenAiChatPromptDriver
from griptape.tasks import PromptTask

task = PromptTask(
    input="User said: {{ args[0] }}",
    prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1"),
)

task.run("Hi there!")
```

Here, `{{ args }}` is rendered at runtime, allowing you to dynamically insert data into the prompt.

For static, key-value data, we can add `context` to our Task:

```
from griptape.drivers.prompt.openai_chat_prompt_driver import OpenAiChatPromptDriver
from griptape.tasks import PromptTask

task = PromptTask(
    input="You are speaking to: {{ user_name }}. User said: {{ args[0] }}",
    prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1"),
    context={"user_name": "Collin"},
)

task.run("Hi there!")
```

These two methods allow you to build more versatile, data-driven prompts. Next, we'll discuss steering the LLM's output using Gen AI Builder's Rule system.

CHAPTER 6

Rules

LLMs can be unpredictable. Getting them to follow specific instructions can be challenging. Gen AI Builder addresses this by providing *Rules and Rulesets* , which offer a structured approach to steering the model's output.

For example, we can create a simple Rule that gives the LLM a name:

```
from griptape.drivers.prompt.openai_chat_prompt_driver import OpenAiChatPromptDriver
from griptape.rules import Rule
from griptape.tasks import PromptTask

task = PromptTask(
    input="You are speaking to: {{ user_name }}. User said: {{ args[0] }}",
    prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1"),
    context={"user_name": "Collin"},
    rules=[Rule("Your name is Oswald.")],
)

task.run("Hi there, whats your name?")
```

Tip

While we typically recommend you stick to Rule-based steering, you can always *override the system prompt* with a custom one. Though pay close attention to the discussed tradeoffs that come with this approach.

Multiple rules can be grouped into `Ruleset` s. Let's refactor our code to use more than one Ruleset:

```
from griptape.drivers.prompt.openai_chat_prompt_driver import OpenAiChatPromptDriver
from griptape.rules import Rule, Ruleset
from griptape.tasks import PromptTask

task = PromptTask(
    input="You are speaking to: {{ user_name }}. User said: {{ args[0] }}",
```

(continues on next page)

(continued from previous page)

```
    prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1"),
    context={"user_name": "Collin"},
    rulesets=[
        Ruleset(
            name="Backstory",
            rules=[
                Rule("Your name is Oswald."),
            ],
        ),
        Ruleset(
            name="Behavior",
            rules=[
                Rule("Introduce yourself at the start of the conversation."),
            ],
        ),
    ],
)

task.run("Hi there!")
```

Gen AI Builder also includes a specialized Rule, *JsonSchemaRule* , which inserts a JSON Schema into the system prompt, ensuring the LLM attempts to return structured, machine-readable data:

```
import json
from typing import TYPE_CHECKING, cast

from griptape.drivers.prompt.openai_chat_prompt_driver import OpenAiChatPromptDriver
from griptape.rules import JsonSchemaRule, Rule, Ruleset
from griptape.tasks import PromptTask

if TYPE_CHECKING:
    from griptape.artifacts.text_artifact import TextArtifact

task = PromptTask(
    input="You are speaking to: {{ user_name }}. User said: {{ args[0] }}",
    prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1"),
    context={"user_name": "Collin"},
    rulesets=[
        Ruleset(
            name="Backstory",
            rules=[
                Rule("Your name is Oswald."),
            ],
        ),
        Ruleset(
            name="Behavior",
            rules=[
                Rule("Introduce yourself at the start of the conversation."),
            ],
        ),
        Ruleset(
            name="Output Format",
```

(continues on next page)

(continued from previous page)

```
            rules=[
                JsonSchemaRule(
                    {
                        "$schema": "https://json-schema.org/draft/2020-12/schema",
                        "type": "object",
                        "properties": {
                            "answer": {"type": "string"},
                        },
                        "required": ["answer"],
                    }
                )
            ],
        ),
    ],
)

task_output_value = cast("TextArtifact", task.run("Hi there!")).value

print(json.dumps(json.loads(task_output_value), indent=2))
```

Note

The *typing.cast* usage is optional, but helps satisfy our type-checker, pyright . We're actively working to improve Gen AI Builder's type hints to avoid clunky casts like this.

Now let's explore an even more robust way to enforce structured outputs.

CHAPTER 7

Structured Output

While a `JsonSchemaRule` can encourage the LLM to return structured data, it doesn't provide guarantees, especially for complex schemas. For stronger enforcement, Gen AI Builder's Prompt Drivers support *Structured Output* .

Structured Output uses the LLM provider's built-in API features to produce outputs in a well-defined schema. It also simplifies parsing, so you can work directly with Python objects rather than manual JSON parsing.

Let's update our Task to use Structured Output:

```
from typing import cast

from pydantic import BaseModel

from griptape.drivers.prompt.openai_chat_prompt_driver import OpenAiChatPromptDriver
from griptape.rules import Rule, Ruleset
from griptape.tasks import PromptTask

class Output(BaseModel):
    answer: str

task = PromptTask(
    input="You are speaking to: {{ user_name }}. User said: {{ args[0] }}",
    prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1"),
    context={"user_name": "Collin"},
    rulesets=[
        Ruleset(
            name="Backstory",
            rules=[
                Rule("Your name is Oswald."),
            ],
        ),
        Ruleset(
            name="Behavior",
            rules=[
```

(continues on next page)

(continued from previous page)

```
                Rule("Introduce yourself at the start of the conversation."),
            ],
        ),
    ],
    output_schema=Output,
)

task_output_value = cast("Output", task.run("Hi there!").value)

print(task_output_value.answer)
```

The LLM response is not only formatted correctly, but automatically parsed into a Python object.

Tip

You can use either pydantic or schema to define your schemas. We recommend pydantic for its ease of use.

Now that we can generate structured responses, let's make our Task more conversational using Gen AI Builder's memory features.

CHAPTER 8

Conversation Memory

By default, each LLM call is stateless. If you want the model to recall previous interactions, use *Conversation Memory*. It tracks Task run history, providing context for the current run.

```
from pydantic import BaseModel

from griptape.drivers.prompt.openai_chat_prompt_driver import OpenAiChatPromptDriver
from griptape.memory.structure import ConversationMemory
from griptape.rules import Rule, Ruleset
from griptape.tasks import PromptTask

class Output(BaseModel):
    answer: str

task = PromptTask(
    input="You are speaking to: {{ user_name }}. User said: {{ args[0] }}",
    prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1"),
    context={"user_name": "Collin"},
    rulesets=[
        Ruleset(
            name="Backstory",
            rules=[
                Rule("Your name is Oswald."),
            ],
        ),
        Ruleset(
            name="Behavior",
            rules=[
                Rule("Introduce yourself at the start of the conversation."),
            ],
        ),
    ],
    output_schema=Output,
```

(continues on next page)

(continued from previous page)

```
    conversation_memory=ConversationMemory(),
)

task.run("Hi there, my name is Collin!")
task.run("Do you remember my name?")
```

Tip

You can customize where the conversation is stored by providing a *Conversation Memory Drivers* .

With that set up, the LLM will now remember our previous exchanges. Let's move on to enabling the model to perform external actions through Tools.

CHAPTER 9

Tools

LLMs themselves cannot browse the internet or perform external actions. You can enable these abilities via *Tools* . A "Tool" is simply a Python class, and any method marked with the `@activity` decorator becomes available to the LLM.

Gen AI Builder comes with a collection of built-in Tools. Below is an example that uses a web search and scrape Tool:

```
from pydantic import BaseModel
from rich.pretty import pprint

from griptape.drivers.prompt.openai_chat_prompt_driver import OpenAiChatPromptDriver
from griptape.drivers.web_search.duck_duck_go import DuckDuckGoWebSearchDriver
from griptape.memory.structure import ConversationMemory
from griptape.rules import Rule, Ruleset
from griptape.tasks import PromptTask
from griptape.tools import WebScraperTool, WebSearchTool

class Feature(BaseModel):
    name: str
    description: str
    emoji: str

class Output(BaseModel):
    answer: str
    key_features: list[Feature]

task = PromptTask(
    id="project-research",
    input="You are speaking to: {{ user_name }}. User said: {{ args[0] }}",
    prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1"),
    context={"user_name": "Collin"},
    rulesets=[
        Ruleset(
```

(continues on next page)

(continued from previous page)

```
            name="Backstory",
            rules=[
                Rule("Your name is Oswald."),
                Rule("You run Oswalds Open Source, a company for helping people learn␣
↪about open source."),
            ],
        ),
        Ruleset(
            name="Behavior",
            rules=[
                Rule("Introduce yourself at the start of the conversation."),
            ],
        ),
    ],
    output_schema=Output,
    tools=[
        WebSearchTool(
            web_search_driver=DuckDuckGoWebSearchDriver(),
        ),
        WebScraperTool(),
    ],
    conversation_memory=ConversationMemory(),
)

output = task.run("Tell me about the python framework Griptape.")

pprint(output.value)
```

Tools are a powerful method for extending the LLM's capabilities. Consider *writing your own Tools* to enable more specialized functionality.

At this point, we have a Task that can handle real-world operations. Now let's look at orchestrating multiple Tasks.

CHAPTER 10

Structures

So far, we've only worked with individual Tasks. As your app becomes more complex, you may want to organize multiple Tasks that execute in sequence or in parallel.

Gen AI Builder provides three Structures:

- **Agent**: A lightweight wrapper around a single `PromptTask`. Great for quick usage but still under the hood is just a `PromptTask`.
- **Pipeline**: Executes Tasks in a specific, linear order.
- **Workflow**: Creates highly parallel DAGs, allowing you to fan out and converge Tasks.

Of the three, `Workflow` is generally the most versatile. `Agent` and `Pipeline` can be handy in certain scenarios but are less frequently needed if you're comfortable just orchestrating Tasks directly.

Let's place our `project-research` Task into a `Workflow` so multiple Tasks can run in parallel:

```
from pydantic import BaseModel
from rich.pretty import pprint

from griptape.drivers.prompt.openai_chat_prompt_driver import OpenAiChatPromptDriver
from griptape.drivers.web_search.duck_duck_go import DuckDuckGoWebSearchDriver
from griptape.rules import Rule, Ruleset
from griptape.structures import Workflow
from griptape.tasks import PromptTask
from griptape.tools import WebScraperTool, WebSearchTool

class Feature(BaseModel):
    name: str
    description: str
    emoji: str

class Output(BaseModel):
    answer: str
    key_features: list[Feature]
```

(continues on next page)

(continued from previous page)

```
projects = ["django", "flask", "fastapi", "litestar"]

workflow = Workflow(
    rulesets=[
        Ruleset(
            name="Backstory",
            rules=[
                Rule("Your name is Oswald."),
                Rule("You run Oswalds Open Source, a company for helping people learn␣
↪about open source."),
            ],
        ),
    ],
)

for project in projects:
    task = PromptTask(
        id=f"project-research-{project}",
        input="Tell me about the open source project: {{ project }}.",
        prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1"),
        context={"project": project},
        output_schema=Output,
        tools=[
            WebSearchTool(
                web_search_driver=DuckDuckGoWebSearchDriver(),
            ),
            WebScraperTool(),
        ],
    )
    workflow.add_task(task)

workflow.run()

for output in workflow.outputs:
    pprint(output.value)
```

10.1 Directly Using PromptSummaryEngine

Engines can be used standalone or integrated into Tasks. To illustrate, let's summarize the outputs of our Workflow:

```
from pydantic import BaseModel

from griptape.artifacts import ListArtifact
from griptape.drivers.prompt.openai_chat_prompt_driver import OpenAiChatPromptDriver
from griptape.drivers.web_search.duck_duck_go import DuckDuckGoWebSearchDriver
from griptape.engines import PromptSummaryEngine
from griptape.rules import Rule, Ruleset
from griptape.structures import Workflow
from griptape.tasks import PromptTask
from griptape.tools import WebScraperTool, WebSearchTool
```

(continues on next page)

(continued from previous page)

```
class Feature(BaseModel):
    name: str
    description: str
    emoji: str

class Output(BaseModel):
    answer: str
    key_features: list[Feature]

projects = ["django", "flask", "fastapi", "litestar"]

workflow = Workflow(
    rulesets=[
        Ruleset(
            name="Backstory",
            rules=[
                Rule("Your name is Oswald."),
                Rule("You run Oswalds Open Source, a company for helping people learn
↪about open source."),
            ],
        ),
    ],
)

for project in projects:
    task = PromptTask(
        id=f"project-research-{project}",
        input="Tell me about the open source project: {{ project }}.",
        prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1"),
        context={"project": project},
        output_schema=Output,
        tools=[
            WebSearchTool(
                web_search_driver=DuckDuckGoWebSearchDriver(),
            ),
            WebScraperTool(),
        ],
    )
    workflow.add_tasks(task)

workflow.run()

summary_engine = PromptSummaryEngine()
summary = summary_engine.summarize_artifacts(ListArtifact(workflow.outputs))

print(summary.value)
```

This produces a concise summary. But one strength of a Workflow is its ability to fan out and converge results. Let's remove the direct `PromptSummaryEngine` usage and use a built-in summary Task instead.

10.2 TextSummaryTask

The *TextSummaryTask* leverages the `PromptSummaryEngine` behind the scenes. We'll have our project-research Tasks converge into one summary Task:

```
from pydantic import BaseModel

from griptape.drivers.prompt.openai_chat_prompt_driver import OpenAiChatPromptDriver
from griptape.drivers.web_search.duck_duck_go import DuckDuckGoWebSearchDriver
from griptape.rules import Rule, Ruleset
from griptape.structures import Workflow
from griptape.tasks import PromptTask, TextSummaryTask
from griptape.tools import WebScraperTool, WebSearchTool

class Feature(BaseModel):
    name: str
    description: str
    emoji: str

class Output(BaseModel):
    answer: str
    key_features: list[Feature]

projects = ["django", "flask", "fastapi", "litestar"]

workflow = Workflow(
    rulesets=[
        Ruleset(
            name="Backstory",
            rules=[
                Rule("Your name is Oswald."),
                Rule("You run Oswalds Open Source, a company for helping people learn␣
↪about open source."),
            ],
        ),
    ],
)

for project in projects:
    task = PromptTask(
        id=f"project-research-{project}",
        input="Tell me about the open source project: {{ project }}.",
        prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1"),
        context={"project": project},
        output_schema=Output,
        tools=[
            WebSearchTool(
                web_search_driver=DuckDuckGoWebSearchDriver(),
            ),
            WebScraperTool(),
        ],
        child_ids=["summary"],
    )
```

(continues on next page)

(continued from previous page)

```
    workflow.add_tasks(task)
workflow.add_task(TextSummaryTask(input="{{ parents_output_text }}", id="summary"))

workflow.run()

print(workflow.output)
```

Finally, let's visualize our Workflow:

```
from pydantic import BaseModel

from griptape.drivers.prompt.openai_chat_prompt_driver import OpenAiChatPromptDriver
from griptape.drivers.web_search.duck_duck_go import DuckDuckGoWebSearchDriver
from griptape.rules import Rule, Ruleset
from griptape.structures import Workflow
from griptape.tasks import PromptTask, TextSummaryTask
from griptape.tools import WebScraperTool, WebSearchTool
from griptape.utils import StructureVisualizer

class Feature(BaseModel):
    name: str
    description: str
    emoji: str

class Output(BaseModel):
    answer: str
    key_features: list[Feature]

projects = ["django", "flask", "fastapi", "litestar"]

workflow = Workflow(
    rulesets=[
        Ruleset(
            name="Backstory",
            rules=[
                Rule("Your name is Oswald."),
                Rule("You run Oswalds Open Source, a company for helping people learn␣
↪about open source."),
            ],
        ),
    ],
)
prompt_driver = OpenAiChatPromptDriver(model="gpt-4.1")

for project in projects:
    task = PromptTask(
        id=f"project-research-{project}",
        input="Tell me about the open source project: {{ project }}.",
        prompt_driver=prompt_driver,
        context={"project": project},
        output_schema=Output,
        tools=[
```

(continues on next page)

(continued from previous page)

```
            WebSearchTool(
                web_search_driver=DuckDuckGoWebSearchDriver(),
            ),
            WebScraperTool(),
        ],
        child_ids=["summary"],
    )
    workflow.add_tasks(task)
workflow.add_task(TextSummaryTask(input="{{ parents_output_text }}", id="summary"))

print(StructureVisualizer(workflow).to_url())
```

Visit the printed URL in your logs to view a diagram illustrating the Workflow's structure:

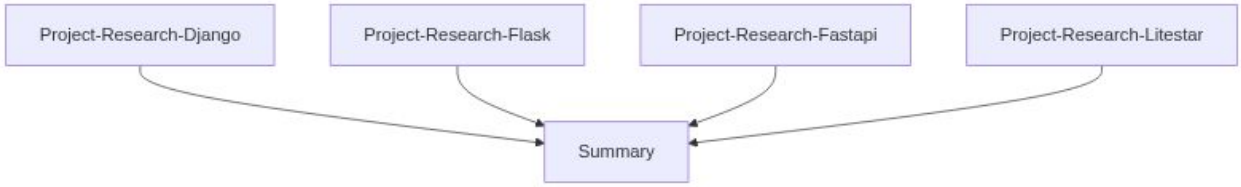

Fig. 1: Workflow Diagram

CHAPTER 11

Conclusion and Next Steps

That's it—you've built your first generative AI application with Gen AI Builder, exploring:

- Simple and advanced Task usage
- Dynamic prompt creation with Jinja templating
- Structured output for more reliable data handling
- Conversation memory for stateful interactions
- Tools for extending LLM capabilities
- Parallel Task orchestration with Workflows
- Text summarization using Engines

This is just the tip of the iceberg. For topic-based guides, continue exploring the Gen AI Builder documentation. For more detailed guides, demos, and advanced techniques, check out Gen AI Builder Tradeschool .

11.1 Data abstractions

11.1.1 Overview

Gen AI Builder provides several abstractions for working with data.

Artifacts are used for passing different types of data, such as text, lists, and blobs, between Gen AI Builder components.

Embedding Drivers are used to generate vector embeddings from text.

Loaders are used to load textual data from different sources.

Chunkers are used to split arbitrarily long text into chunks of certain token length.

Tokenizers are used to tokenize and detokenize text in order to track LLM token limits.

RAG Engines are used for implementing modular RAG pipelines.

Extraction Engines are used for extracting structured content.

Summary Engines are used for summarizing text content.

Vector Store Drivers are used to store and query vector databases.

Prompt Drivers are used to call LLM APIs.

Artifacts

Overview

** *Artifacts* ** are the core data structure in Gen AI Builder. They are used to encapsulate data and enhance it with metadata.

Text

TextArtifact s store textual data. They offer methods such as *token_count()* for counting tokens with a tokenizer, and *generate_embedding()* for creating text embeddings. You can also access the embedding via the *Embedding* property.

When `TextArtifact` s are returned from Tools, they will be stored in *Task Memory and Off Prompt* if the Tool has set `off_prompt=True` .

Blob

BlobArtifact s store binary large objects (blobs).

When `BlobArtifact` s are returned from Tools, they will be stored in *Task Memory and Off Prompt* if the Tool has set `off_prompt=True` .

Image

ImageArtifact s store image data. This includes binary image data along with metadata such as MIME type and dimensions. They are a subclass of *BlobArtifactStorage* .

Url

ImageUrlArtifact s store URLs pointing to resources.

Image Url

ImageUrlArtifact s store URLs pointing to images. They are a subclass of *ImageUrlArtifact* .

Audio

AudioArtifact s store audio content. This includes binary audio data and metadata such as format, and duration. They are a subclass of *BlobArtifactStorage* .

List

ListArtifact s store lists of Artifacts.

When `ListArtifact` s are returned from Tools, their elements will be stored in *Task Memory and Off Prompt* if the element is either a `TextArtifact` or a `BlobArtifact` and the Tool has set `off_prompt=True` .

Info

InfoArtifact s store small pieces of textual information. These are useful for conveying messages about the execution or results of an operation, such as “No results found” or “Operation completed successfully.”

JSON

JsonArtifact s store JSON-serializable data. Any data assigned to the `value` property is processed using `json.dumps(json.loads(value))`.

Error

ErrorArtifact s store exception information, providing a structured way to convey errors.

Action

ActionArtifact s represent actions taken by an LLM. Currently, the only supported action type is *ToolAction* , which is used to execute a *RAG Tool* .

Generic

GenericArtifact s provide a flexible way to pass data that does not fit into any other artifact category. While not generally recommended, they can be useful for specific use cases. For instance, see talking to a video, which demonstrates using a `GenericArtifact` to pass a Gemini-specific video file.

Chunkers

Overview

Chunkers are used to split arbitrarily long text into chunks of certain token length. Each chunker has a tokenizer, a max token count, and a list of default separators used to split up text into *TextArtifact* s. Different types of chunkers provide lists of separators for specific text shapes:

- `:ref:`TextChunker <TextChunker>`  : works on most texts.`
- `:ref:`PdfChunker <PdfChunker>`  : works on text from PDF docs.`
- `:ref:`MarkdownChunker <MarkdownChunker>`  works on markdown text.`

Here is how to use a chunker:

```
from griptape.chunkers import TextChunker
from griptape.tokenizers import OpenAiTokenizer

TextChunker(
    # set an optional custom tokenizer
    tokenizer=OpenAiTokenizer(model="gpt-4.1"),
    # optionally modify default number of tokens
    max_tokens=100,
).chunk("long text")
```

The most common use of a Chunker is to split up a long text into smaller chunks for inserting into a Vector Database when doing Retrieval Augmented Generation (RAG).

See *RagEngine* for more information on how to use Chunkers in RAG pipelines.

Loaders

Overview

Loaders are used to load data from sources and parse it into *Artifacts* s. Each loader can be used to load a single "source" with *load()* or multiple sources with *load_collection()* .

File

The following Loaders load a file using a *AmazonS3FileManagerDriver* and loads the resulting data into an *Artifacts* for the respective file type.

As a convenience, File Loaders also have a `save()` method that can save an Artifact to a destination.

```
from griptape.drivers.file_manager.local import LocalFileManagerDriver
from griptape.loaders import TextLoader

loader = TextLoader(file_manager_driver=LocalFileManagerDriver())

data = loader.load("tests/resources/test.txt")

data.value = data.value.replace("foo", "bar")

loader.save("tests/resources/test.txt", data)
```

Text

Loads text files into *TextArtifact* s:

```
import urllib.request
from pathlib import Path

from griptape.loaders import TextLoader

TextLoader().load("tests/resources/test.txt")

urllib.request.urlretrieve("https://example-files.online-convert.com/document/txt/
↪example.txt", "example.txt")

TextLoader().load(Path("example.txt"))

TextLoader().load_collection(["tests/resources/test.txt", Path("example.txt")])
```

PDF

Loads PDF files into *ListArtifact* s, where each element is a *TextArtifact* containing a page of the PDF:

```
import urllib.request
from pathlib import Path

from griptape.loaders import PdfLoader

urllib.request.urlretrieve("https://arxiv.org/pdf/1706.03762.pdf", "attention.pdf")
```

(continues on next page)

(continued from previous page)

```
#  Load a single PDF file

PdfLoader().load("attention.pdf")

#  You can also pass a Path object

PdfLoader().load(Path("attention.pdf"))

urllib.request.urlretrieve("https://arxiv.org/pdf/1706.03762.pdf", "CoT.pdf")

#  Load multiple PDF files

PdfLoader().load_collection([Path("attention.pdf"), Path("CoT.pdf")])
```

CSV

Loads CSV files into *ListArtifact* s, where each element is a *TextArtifact* containing a row of the CSV:

```
from pathlib import Path

from griptape.loaders import CsvLoader

#  Load a single CSV file

CsvLoader().load("tests/resources/cities.csv")

#  You can also pass a Path object

CsvLoader().load(Path("tests/resources/cities.csv"))

#  Load multiple CSV files

CsvLoader().load_collection([Path("tests/resources/cities.csv"), "tests/resources/
↪addresses.csv"])
```

Image

Loads images into *ImageArtifact* s:

```
from pathlib import Path

from griptape.loaders import ImageLoader

#  Load an image from disk

ImageLoader().load("tests/resources/mountain.png")

#  You can also pass a Path object

ImageLoader().load(Path("tests/resources/mountain.png"))
```

By default, the Image Loader will load images in their native format, but not all models work on all formats. To

normalize the format of Artifacts returned by the Loader, set the `format` field.

```
from pathlib import Path

from griptape.loaders import ImageLoader

#  Load a single image in BMP format

ImageLoader(format="bmp").load("tests/resources/mountain.png")

#  You can also pass a Path object

ImageLoader(format="bmp").load(Path("tests/resources/mountain.png"))

#  Load multiple images in BMP format

ImageLoader().load_collection([Path("tests/resources/mountain.png"), "tests/resources/
↪cow.png"])
```

Audio

Loads audio files into *AudioArtifact* s:

The Loader will load audio in its native format and populates the resulting Artifact's `format` field by making a best-effort guess of the underlying audio format using the `filetype` package.

```
from pathlib import Path

from griptape.loaders import AudioLoader

#  Load an image from disk

AudioLoader().load("tests/resources/sentences.wav")

#  You can also pass a Path object

AudioLoader().load(Path("tests/resources/sentences.wav"))
```

JSON

Loads JSON files into *JsonArtifact* s:

```
from pathlib import Path

from griptape.loaders import JsonLoader

#  Load an image from disk

JsonLoader().load("tests/resources/test.json")

#  You can also pass a Path object

JsonLoader().load(Path("tests/resources/test.json"))
```

Web

Scrapes web pages using a *BaseWebScraperDriver* and loads the resulting text into *TextArtifact* s.

```
from griptape.loaders import WebLoader

WebLoader().load("https://www.griptape.ai")

WebLoader().load_collection(["https://www.griptape.ai", "https://docs.griptape.ai"])
```

SQL

Loads data from a SQL database using a *AmazonRedshiftSqlDriver* and loads the resulting data into *ListArtifact* s, where each element is a *TextArtifact* containing a row of the SQL query.

```
from griptape.drivers.sql.sql_driver import SqlDriver
from griptape.loaders import SqlLoader

SqlLoader(sql_driver=SqlDriver(engine_url="sqlite:///:memory:")).load("SELECT foo, bar
↪")

SqlLoader(sql_driver=SqlDriver(engine_url="sqlite:///:memory:")).load_collection(
    ["SELECT foo, bar;", "SELECT fizz, buzz;"]
)
```

Email

Loads data from an imap email server into a *ListArtifact* s, where each element is a *TextArtifact* containing an email.

```
from griptape.loaders import EmailLoader

loader = EmailLoader(imap_url="an.email.server.hostname", username="username",␣
↪password="password")

loader.load(EmailLoader.EmailQuery(label="INBOX"))

loader.load_collection([EmailLoader.EmailQuery(label="INBOX"), EmailLoader.
↪EmailQuery(label="SENT")])
```

11.2 Prompt

11.2.1 Overview

Prompt Drivers are used by Gen AI Builder Structures to make API calls to the underlying LLMs. *OpenAI Chat* is the default prompt driver used in all structures.

You can instantiate drivers and pass them to structures:

```
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.rules import Rule
from griptape.structures import Agent

agent = Agent(
```

(continues on next page)

(continued from previous page)

```
    prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1", temperature=0.3),
    input="You will be provided with a tweet, and your task is to classify its␣
↪sentiment as positive, neutral, or negative. Tweet: {{ args[0] }}",
    rules=[Rule(value="Output only the sentiment.")],
)

agent.run("I loved the new Batman movie!")
```

Or use them independently:

```
from griptape.common import PromptStack
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver

stack = PromptStack()

stack.add_system_message("You will be provided with Python code, and your task is to␣
↪calculate its time complexity.")
stack.add_user_message(
    """
    def foo(n, k):
        accum = 0
        for i in range(n):
            for l in range(k):
                accum += i
        return accum
    """
)

result = OpenAiChatPromptDriver(model="gpt-3.5-turbo-16k", temperature=0).run(stack)

print(result.value)
```

You can pass images to the Driver if the model supports it:

```
from griptape.artifacts import ListArtifact, TextArtifact
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.loaders import ImageLoader

driver = OpenAiChatPromptDriver(model="gpt-4.1", max_tokens=256)

image_artifact = ImageLoader().load("./tests/resources/mountain.jpg")
text_artifact = TextArtifact("Describe the weather in the image")

driver.run(ListArtifact([text_artifact, image_artifact]))
```

11.2.2 Structured Output

Some LLMs provide functionality often referred to as “Structured Output”. This means instructing the LLM to output data in a particular format, usually JSON. This can be useful for forcing the LLM to output in a parsable format that can be used by downstream systems.

> **Warning**
>
> Each Driver may have a different default setting depending on the LLM provider's capabilities.

Prompt Task

The easiest way to get started with structured output is by using a *PromptTask* 's *default_run_output_schema_validation_subtasks(subtask_input)* parameter.

You can change *how* the output is structured by setting the Driver's validate*structured_output_strategy(*, value) to one of:

- `native` : The Driver will use the LLM's structured output functionality provided by the API.
- `tool` : The Driver will add a special tool, *StructuredOutputTool* , and will try to force the LLM to use the Tool.
- `rule` : The Driver will add a *JsonSchemaRule* to the Task's system prompt. This strategy does not guarantee that the LLM will output JSON and should only be used as a last resort.

You can specify `output_schema` using either `pydantic` or `schema` libraries, though `pydantic` is recommended.

```
from pydantic import BaseModel
from rich.pretty import pprint

from griptape.rules import Rule
from griptape.structures import Pipeline
from griptape.tasks import PromptTask

class Step(BaseModel):
    explanation: str
    output: str

class Output(BaseModel):
    steps: list[Step]
    final_answer: str

pipeline = Pipeline(
    tasks=[
        PromptTask(
            output_schema=Output,
            rules=[
                Rule("You are a helpful math tutor. Guide the user through the␣
↪solution step by step."),
            ],
        )
    ]
)

output = pipeline.run("How can I solve 8x + 7 = -23").output.value

pprint(output)  # OutputModel
```

```
import schema
from rich.pretty import pprint
```

(continues on next page)

(continued from previous page)

```
from griptape.rules import Rule
from griptape.structures import Pipeline
from griptape.tasks import PromptTask

pipeline = Pipeline(
    tasks=[
        PromptTask(
            output_schema=schema.Schema(
                {
                    "steps": [schema.Schema({"explanation": str, "output": str})],
                    "final_answer": str,
                }
            ),
            rules=[
                Rule("You are a helpful math tutor. Guide the user through the␣
↪solution step by step."),
            ],
        )
    ]
)

output = pipeline.run("How can I solve 8x + 7 = -23").output.value

pprint(output)  # dict
pprint(output["steps"])
```

11.2.3 Prompt Drivers

Gen AI Builder offers the following Prompt Drivers for interacting with LLMs.

OpenAI Chat

The *AzureOpenAiChatPromptDriver* connects to the OpenAI Chat API. This driver uses *OpenAi function calling* when using *Tools* .

```
import os

from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.structures import Agent

agent = Agent(
    prompt_driver=OpenAiChatPromptDriver(
        api_key=os.environ["OPENAI_API_KEY"],
        model="gpt-4.1",
        temperature=0.1,
        seed=42,
    ),
    input="You will be provided with a description of a mood, and your task is to␣
↪generate the CSS color code for a color that matches it. Description: {{ args[0] }}
↪",
)
```

(continues on next page)

(continued from previous page)

```
agent.run("Blue sky at dusk.")
```

`

OpenAi's *reasoning models* can also be used, and come with an additional parameter: *reasoning_effort* .

```
import os

from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.structures import Agent

agent = Agent(
    prompt_driver=OpenAiChatPromptDriver(
        api_key=os.environ["OPENAI_API_KEY"],
        model="o3-mini",
        reasoning_effort="medium",
    ),
)

agent.run("""Write a bash script that takes a matrix represented as a string with
format [1,2],[3,4],[5,6] and prints the transpose in the same format.""")
```

OpenAI Compatible

Many services such as LMStudio and OhMyGPT provide OpenAI-compatible APIs. You can use the *AzureOpenAiChatPromptDriver* to interact with these services. Simply set the `base_url` to the service's API endpoint and the `model` to the model name. If the service requires an API key, you can set it in the `api_key` field.

For example, here is how we can connect to LMStudio's API:

```
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.rules import Rule
from griptape.structures import Agent

agent = Agent(
    prompt_driver=OpenAiChatPromptDriver(
        base_url="http://127.0.0.1:1234/v1", model="lmstudio-community/Meta-Llama-3-
↪8B-Instruct-GGUF", stream=True
    ),
    rules=[Rule(value="You are a helpful coding assistant.")],
)

agent.run("How do I init and update a git submodule?")
```

Or Groq's API:

```
import os

from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.structures import Agent

agent = Agent(
    prompt_driver=OpenAiChatPromptDriver(
```

(continues on next page)

(continued from previous page)

```
        api_key=os.environ["GROQ_API_KEY"],
        base_url="https://api.groq.com/openai/v1",
        model="llama-3.3-70b-versatile",
    ),
)

agent.run("Hello")
```

Tip

Make sure to include *v1* at the end of the *base_url* to match the OpenAI API endpoint.

Azure OpenAI Chat

The *AzureOpenAiChatPromptDriver* connects to Azure OpenAI *Chat Completion* APIs. This driver uses *Azure OpenAi function calling* when using *Tools* .

```
import os

from griptape.drivers.prompt.openai import AzureOpenAiChatPromptDriver
from griptape.rules import Rule
from griptape.structures import Agent

agent = Agent(
    prompt_driver=AzureOpenAiChatPromptDriver(
        api_key=os.environ["AZURE_OPENAI_API_KEY_1"],
        model="gpt-4.1",
        azure_endpoint=os.environ["AZURE_OPENAI_ENDPOINT_1"],
    ),
    rules=[
        Rule(
            value="You will be provided with text, and your task is to translate it␣
↪into emojis. "
            "Do not use any regular text. Do your best with emojis only."
        )
    ],
)

agent.run("Artificial intelligence is a technology with great promise.")
```

Gen AI Builder

The *GriptapeCloudPromptDriver* connects to the Gen AI Builder chat messages API.

```
import os

from griptape.drivers.prompt.griptape_cloud import GriptapeCloudPromptDriver
from griptape.rules import Rule
from griptape.structures import Agent

agent = Agent(
```

(continues on next page)

(continued from previous page)

```
    prompt_driver=GriptapeCloudPromptDriver(
        api_key=os.environ["GT_CLOUD_API_KEY"],
    ),
    rules=[
        Rule(
            "You will be provided with a product description and seed words, and your␣
↪task is to generate product names.",
        ),
    ],
)

agent.run("Product description: A home milkshake maker. Seed words: fast, healthy,␣
↪compact.")
```

Cohere

The *CoherePromptDriver* connects to the Cohere Chat API. This driver uses *Cohere tool use* when using *Tools* .

```
import os

from griptape.drivers.prompt.cohere import CoherePromptDriver
from griptape.structures import Agent

agent = Agent(
    prompt_driver=CoherePromptDriver(
        model="command-r",
        api_key=os.environ["COHERE_API_KEY"],
    )
)

agent.run(What is the sentiment of this review? Review: "I really enjoyed this movie!
↪")
```

Anthropic

The *AnthropicPromptDriver* connects to the Anthropic Messages API. This driver uses *Anthropic tool use* when using *Tools* .

```
import os

from griptape.drivers.prompt.anthropic import AnthropicPromptDriver
from griptape.structures import Agent

agent = Agent(
    prompt_driver=AnthropicPromptDriver(
        model="claude-3-opus-20240229",
        api_key=os.environ["ANTHROPIC_API_KEY"],
    )
)

agent.run("Where is the best place to see cherry blossums in Japan?")
```

Google

The *GooglePromptDriver* connects to the Google Generative AI <Optional title for the content. Only works with `retrieval_document task type.>` API. This driver uses Gemini function calling <Optional title for the content. Only works with `retrieval_document task type.>` when using *Tools* .

```
import os

from griptape.drivers.prompt.google import GooglePromptDriver
from griptape.structures import Agent

agent = Agent(
    prompt_driver=GooglePromptDriver(
        model="gemini-2.0-flash",
        api_key=os.environ["GOOGLE_API_KEY"],
    )
)

agent.run("Briefly explain how a computer works to a young child.")
```

Amazon Bedrock

The *AmazonBedrockPromptDriver* uses Amazon Bedrock 's *Converse API* . This driver uses *Bedrock tool use* when using *Tools* .

All models supported by the Converse API are available for use with this driver.

```
from griptape.drivers.prompt.amazon_bedrock import AmazonBedrockPromptDriver
from griptape.rules import Rule
from griptape.structures import Agent

agent = Agent(
    prompt_driver=AmazonBedrockPromptDriver(
        model="anthropic.claude-3-sonnet-20240229-v1:0",
    ),
    rules=[
        Rule(
            value="You are a customer service agent that is classifying emails by␣
↪type. I want you to give your answer and then explain it."
        )
    ],
)
agent.run(
    """How would you categorize this email?
    <email>
    Can I use my Mixmaster 4000 to mix paint, or is it only meant for mixing food?
    </email>

    Categories are:
    (A) Pre-sale question
    (B) Broken or defective item
    (C) Billing question
    (D) Other (please explain)"""
)
```

Ollama

The *OllamaPromptDriver* connects to the *Ollama Chat Completion API* . This driver uses *Ollama tool calling* when using *Tools* .

```
from griptape.drivers.prompt.ollama import OllamaPromptDriver
from griptape.structures import Agent
from griptape.tools import CalculatorTool

agent = Agent(
    prompt_driver=OllamaPromptDriver(
        model="llama3.1",
    ),
    tools=[CalculatorTool()],
)
agent.run("What is (192 + 12) ^ 4")
```

Hugging Face Hub

The *HuggingFaceHubPromptDriver* connects to the Hugging Face Hub API .

Warning

Not all models featured on the Hugging Face Hub are supported by this driver. Models that are not supported by *Hugging Face serverless inference* will not work with this driver. Due to the limitations of Hugging Face serverless inference, only models that are than 10GB are supported.

```
import os

from griptape.drivers.prompt.huggingface_hub import HuggingFaceHubPromptDriver
from griptape.rules import Rule, Ruleset
from griptape.structures import Agent

agent = Agent(
    prompt_driver=HuggingFaceHubPromptDriver(
        model="HuggingFaceH4/zephyr-7b-beta",
        api_token=os.environ["HUGGINGFACE_HUB_ACCESS_TOKEN"],
    ),
    rulesets=[
        Ruleset(
            name="Girafatron",
            rules=[
                Rule(
                    value="You are Girafatron, a giraffe-obsessed robot. You are␣
↪talking to a human. "
                    "Girafatron is obsessed with giraffes, the most glorious animal␣
↪on the face of this Earth. "
                    "Giraftron believes all other animals are irrelevant when␣
↪compared to the glorious majesty of the giraffe."
                )
            ],
        )
```

(continues on next page)

(continued from previous page)

```
    ],
)

agent.run("Hello Girafatron, what is your favorite animal?")
```

Text Generation Interface

The *HuggingFaceHubPromptDriver* also supports Text Generation Interface for running models locally. To use Text Generation Interface, just set `model` to a TGI endpoint.

```
import os

from griptape.drivers.prompt.huggingface_hub import HuggingFaceHubPromptDriver
from griptape.structures import Agent

agent = Agent(
    prompt_driver=HuggingFaceHubPromptDriver(
        model="http://127.0.0.1:8080",
        api_token=os.environ["HUGGINGFACE_HUB_ACCESS_TOKEN"],
    ),
)

agent.run("Write the code for a snake game.")
```

Hugging Face Pipeline

The *HuggingFacePipelinePromptDriver* uses *Hugging Face Pipelines* for inference locally.

> **Warning**
>
> Running a model locally can be a computationally expensive process.

```
from griptape.drivers.prompt.huggingface_pipeline import␣
↪HuggingFacePipelinePromptDriver
from griptape.rules import Rule, Ruleset
from griptape.structures import Agent

agent = Agent(
    prompt_driver=HuggingFacePipelinePromptDriver(
        model="TinyLlama/TinyLlama-1.1B-Chat-v1.0",
    ),
    rulesets=[
        Ruleset(
            name="Pirate",
            rules=[Rule(value="You are a pirate chatbot who always responds in pirate␣
↪speak!")],
        )
    ],
)

agent.run("How many helicopters can a human eat in one sitting?")
```

Amazon SageMaker Jumpstart

The *AmazonSageMakerJumpstartPromptDriver* uses Amazon SageMaker Jumpstart for inference on AWS.

Amazon Sagemaker Jumpstart provides a wide range of models with varying capabilities. This Driver has been primarily *chat-optimized* models that have a *Huggingface Chat Template* available. If your model does not fit this use-case, we suggest sub-classing *AmazonSageMakerJumpstartPromptDriver* and overriding the `_to_model_input` and `_to_model_params` methods.

```
import os

from griptape.drivers.prompt.amazon_sagemaker_jumpstart import␣
↪AmazonSageMakerJumpstartPromptDriver
from griptape.structures import Agent

agent = Agent(
    prompt_driver=AmazonSageMakerJumpstartPromptDriver(
        endpoint=os.environ["SAGEMAKER_LLAMA_3_INSTRUCT_ENDPOINT_NAME"],
        model="meta-llama/Meta-Llama-3-8B-Instruct",
    )
)

agent.run("What is a good lasagna recipe?")
```

Grok

The *GrokPromptDriver* uses *Grok's chat completion* endpoint.

```
import os

from griptape.drivers.prompt.grok import GrokPromptDriver
from griptape.rules import Rule
from griptape.structures import Agent

agent = Agent(
    prompt_driver=GrokPromptDriver(model="grok-2-latest", api_key=os.environ["GROK_
↪API_KEY"]),
    rules=[Rule("You are Grok, a chatbot inspired by the Hitchhikers Guide to the␣
↪Galaxy.")],
)

agent.run("What is the meaning of life, the universe, and everything?")
```

Perplexity

The *PerplexityPromptDriver* uses *Perplexity Sonar's chat completion* endpoint.

While you can use this Driver directly, we recommend using it through its accompanying *Web Search Drivers* .

```
import os

from griptape.drivers.prompt.perplexity import PerplexityPromptDriver
from griptape.rules import Rule
from griptape.structures import Agent
from griptape.tasks import PromptTask
```

(continues on next page)

(continued from previous page)

```
agent = Agent(
    tasks=[
        PromptTask(
            prompt_driver=PerplexityPromptDriver(model="sonar-pro", api_key=os.
↪environ["PERPLEXITY_API_KEY"]),
            rules=[
                Rule("Be precise and concise"),
            ],
        )
    ],
)

agent.run("How many stars are there in our galaxy?")
```

Assistant

Overview

Assistant Drivers can be used to interact with various "assistant" services.

Assistant Drivers

Gen AI Builder

The *GriptapeCloudAssistantDriver* is used to run Gen AI Builder Assistants.

```
import os

from griptape.drivers.assistant.griptape_cloud import GriptapeCloudAssistantDriver
from griptape.structures import Pipeline
from griptape.tasks import AssistantTask
from griptape.utils.stream import Stream

pipeline = Pipeline(
    tasks=[
        AssistantTask(
            assistant_driver=GriptapeCloudAssistantDriver(
                assistant_id=os.environ["GT_CLOUD_ASSISTANT_ID"],
                stream=True,
            ),
        ),
    ]
)

for chunk in Stream(pipeline).run("Write me long poem"):
    print(chunk, end="", flush=True)
```

OpenAI

The *OpenAiAssistantDriver* is used to run *OpenAI Assistants* .

```
import os

from griptape.drivers.assistant.openai import OpenAiAssistantDriver
from griptape.structures import Pipeline
from griptape.tasks import AssistantTask
from griptape.utils.stream import Stream

pipeline = Pipeline(
    tasks=[
        AssistantTask(
            assistant_driver=OpenAiAssistantDriver(
                assistant_id=os.environ["OPENAI_ASSISTANT_ID"], thread_id=os.environ[
↪"OPENAI_THREAD_ID"]
            ),
        ),
    ]
)

for chunk in Stream(pipeline).run("I need to solve the equation `3x + 11 = 14`. Can␣
↪you help me?"):
    print(chunk, end="", flush=True)
```

Audio Transcription

Overview

Audio Transcription Drivers extract text from spoken audio.

Audio Transcription Drivers

OpenAI

The *OpenAI Audio Transcription Driver* utilizes OpenAI's sophisticated `whisper` model to accurately transcribe spoken audio into text. This model supports multiple languages, ensuring precise transcription across a wide range of dialects.

```
from griptape.drivers.audio_transcription.openai import OpenAiAudioTranscriptionDriver
from griptape.structures import Agent
from griptape.tools.audio_transcription.tool import AudioTranscriptionTool

driver = OpenAiAudioTranscriptionDriver(model="whisper-1")

tool = AudioTranscriptionTool(
    off_prompt=False,
    audio_transcription_driver=driver,
)

Agent(tools=[tool]).run("Transcribe the following audio file: tests/resources/
↪sentences.wav")
```

Conversation Memory

Overview

You can persist and load memory by using Conversation Memory Drivers. You can build drivers for your own data stores by extending *BaseConversationMemoryDriver* .

Conversation Memory Drivers

Gen AI Builder

The *GriptapeCloudConversationMemoryDriver* allows you to persist Conversation Memory in Gen AI Builder. It provides seamless integration with Gen AI Builder's cloud-based `Threads` and `Messages` resources.

```
import os

from griptape.drivers.memory.conversation.griptape_cloud import␣
↪GriptapeCloudConversationMemoryDriver
from griptape.memory.structure import ConversationMemory
from griptape.structures import Agent

cloud_conversation_driver = GriptapeCloudConversationMemoryDriver(
    api_key=os.environ["GT_CLOUD_API_KEY"],
    alias="my_thread_alias",
)
agent = Agent(conversation_memory=ConversationMemory(conversation_memory_driver=cloud_
↪conversation_driver))

agent.run("My name is Jeff.")
agent.run("What is my name?")
```

Local

The *LocalConversationMemoryDriver* allows you to persist Conversation Memory in a local JSON file.

```
from griptape.drivers.memory.conversation.local import LocalConversationMemoryDriver
from griptape.memory.structure import ConversationMemory
from griptape.structures import Agent

local_driver = LocalConversationMemoryDriver(persist_file="memory.json")
agent = Agent(conversation_memory=ConversationMemory(conversation_memory_driver=local_
↪driver))

agent.run("Surfing is my favorite sport.")
agent.run("What is my favorite sport?")
```

Amazon DynamoDb

The *AmazonDynamoDbConversationMemoryDriver* allows you to persist Conversation Memory in Amazon DynamoDb .

```
import os
import uuid
```

(continues on next page)

(continued from previous page)

```
from griptape.drivers.memory.conversation.amazon_dynamodb import␣
↪AmazonDynamoDbConversationMemoryDriver
from griptape.memory.structure import ConversationMemory
from griptape.structures import Agent

conversation_id = uuid.uuid4().hex
dynamodb_driver = AmazonDynamoDbConversationMemoryDriver(
    table_name=os.environ["DYNAMODB_TABLE_NAME"],
    partition_key="id",
    value_attribute_key="memory",
    partition_key_value=conversation_id,
)

agent = Agent(conversation_memory=ConversationMemory(conversation_memory_
↪driver=dynamodb_driver))

agent.run("My name is Jeff.")
agent.run("What is my name?")
```

Optional parameters `sort_key` and `sort_key_value` can be supplied for tables with a composite primary key.

Redis

The *RedisConversationMemoryDriver* allows you to persist Conversation Memory in Redis .

```
import os
import uuid

from griptape.drivers.memory.conversation.redis import RedisConversationMemoryDriver
from griptape.memory.structure import ConversationMemory
from griptape.structures import Agent

conversation_id = uuid.uuid4().hex
redis_conversation_driver = RedisConversationMemoryDriver(
    host=os.environ["REDIS_HOST"],
    port=int(os.environ["REDIS_PORT"]),
    username=os.environ["REDIS_USERNAME"],
    password=os.environ["REDIS_PASSWORD"],
    index=os.environ["REDIS_INDEX"],
    conversation_id=conversation_id,
)

agent = Agent(conversation_memory=ConversationMemory(conversation_memory_driver=redis_
↪conversation_driver))

agent.run("My name is Jeff.")
agent.run("What is my name?")
```

Embedding

Overview

Embeddings in Gen AI Builder are multidimensional representations of text or image data. Embeddings carry semantic information, making them powerful for use-cases like text or image similarity search in a *RAG Engine* .

Embedding Drivers

OpenAI

The *OpenAiEmbeddingDriver* uses the *OpenAI Embeddings API* .

```
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver

embeddings = OpenAiEmbeddingDriver().embed("Hello Griptape!")

#  display the first 3 embeddings

print(embeddings[:3])
```

```
[0.0017853748286142945, 0.006118456833064556, -0.005811543669551611]
```

OpenAI Compatible

Many services such as LMStudio and OhMyGPT provide OpenAI-compatible APIs. You can use the *OpenAiEmbeddingDriver* to interact with these services. Simply set the `base_url` to the service's API endpoint and the `model` to the model name. If the service requires an API key, you can set it in the `api_key` field.

```
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver

embedding_driver = OpenAiEmbeddingDriver(
    base_url="http://127.0.0.1:1234/v1",
    model="nomic-ai/nomic-embed-text-v1.5-GGUF/nomic-embed-text-v1.5.Q2_K",
)

embeddings = embedding_driver.embed("Hello world!")

#  display the first 3 embeddings

print(embeddings[:3])
```

> **Tip**
>
> Make sure to include *v1* at the end of the *base_url* to match the OpenAI API endpoint.

Azure OpenAI

The *AzureOpenAiEmbeddingDriver* uses the same parameters as *OpenAiEmbeddingDriver*

with updated defaults.

Bedrock Titan

The *AmazonBedrockTitanEmbeddingDriver* uses the Amazon Bedrock Embeddings API .

```
from griptape.drivers.embedding.amazon_bedrock import␣
↪AmazonBedrockTitanEmbeddingDriver
from griptape.loaders import ImageLoader

embedding_driver = AmazonBedrockTitanEmbeddingDriver()
embeddings = embedding_driver.embed("Hello world!")

print(embeddings[:3])

#  Some models support images!

multi_modal_embedding_driver = AmazonBedrockTitanEmbeddingDriver(model="amazon.titan-
↪embed-image-v1")
image = ImageLoader().load("tests/resources/cow.png")
image_embeddings = multi_modal_embedding_driver.embed(image)

print(image_embeddings[:3])
```

```
[-0.234375, -0.024902344, -0.14941406]
```

Google

The *GoogleEmbeddingDriver* uses the Google Embeddings API <Optional title for the content. Only works with `retrieval_document task type.>` .

```
from griptape.drivers.embedding.google import GoogleEmbeddingDriver

embeddings = GoogleEmbeddingDriver().embed("Hello world!")

#  display the first 3 embeddings

print(embeddings[:3])
```

```
[0.0588633, 0.0033929371, -0.072810836]
```

Hugging Face Hub

The *HuggingFaceHubEmbeddingDriver* connects to the Hugging Face Hub API . It supports models with the following tasks:

- feature-extraction

```
import os

from griptape.drivers.embedding.huggingface_hub import HuggingFaceHubEmbeddingDriver
from griptape.tokenizers import HuggingFaceTokenizer

driver = HuggingFaceHubEmbeddingDriver(
    api_token=os.environ["HUGGINGFACE_HUB_ACCESS_TOKEN"],
```

(continues on next page)

(continued from previous page)

```
    model="sentence-transformers/all-MiniLM-L6-v2",
    tokenizer=HuggingFaceTokenizer(
        model="sentence-transformers/all-MiniLM-L6-v2",
        max_output_tokens=512,
    ),
)

embeddings = driver.embed("Hello world!")

#  display the first 3 embeddings

print(embeddings[:3])
```

Ollama

The *OllamaEmbeddingDriver* uses the *Ollama Embeddings API* .

```
from griptape.drivers.embedding.ollama import OllamaEmbeddingDriver

driver = OllamaEmbeddingDriver(
    model="all-minilm",
)

results = driver.embed("Hello world!")

#  display the first 3 embeddings

print(results[:3])
```

Amazon SageMaker Jumpstart

The *AmazonSageMakerJumpstartEmbeddingDriver* uses the Amazon SageMaker Endpoints to generate embeddings on AWS.

```
import os

from griptape.drivers.embedding.amazon_sagemaker_jumpstart import␣
↪AmazonSageMakerJumpstartEmbeddingDriver

driver = AmazonSageMakerJumpstartEmbeddingDriver(
    endpoint=os.environ["SAGEMAKER_ENDPOINT"],
    model=os.environ["SAGEMAKER_TENSORFLOW_HUB_MODEL"],
)

embeddings = driver.embed("Hello world!")

#  display the first 3 embeddings

print(embeddings[:3])
```

VoyageAI

The *VoyageAiEmbeddingDriver* uses the *VoyageAI Embeddings API* .

```
import os

from griptape.drivers.embedding.voyageai import VoyageAiEmbeddingDriver
from griptape.loaders import ImageLoader

embedding_driver = VoyageAiEmbeddingDriver(api_key=os.environ["VOYAGE_API_KEY"])
embeddings = embedding_driver.embed("Hello world!")

print(embeddings[:3])

#  Some models support images!

multi_modal_embedding_driver = VoyageAiEmbeddingDriver(
    api_key=os.environ["VOYAGE_API_KEY"], model="voyage-multimodal-3"
)
image = ImageLoader().load("tests/resources/cow.png")
image_embeddings = multi_modal_embedding_driver.embed(image)

print(image_embeddings[:3])
```

Cohere

The *CohereEmbeddingDriver* uses the *Cohere Embeddings API* .

```
import os

from griptape.drivers.embedding.cohere import CohereEmbeddingDriver

embedding_driver = CohereEmbeddingDriver(
    model="embed-english-v3.0",
    api_key=os.environ["COHERE_API_KEY"],
    input_type="search_document",
)

embeddings = embedding_driver.embed("Hello world!")

#  display the first 3 embeddings

print(embeddings[:3])
```

Nvidia NIM

The *NvidiaNimEmbeddingDriver* uses the Nvidia NIM API .

Override Default Structure Embedding Driver

Here is how you can override the Embedding Driver that is used by default in Structures.

```
from griptape.configs import Defaults
from griptape.configs.drivers import DriversConfig
from griptape.drivers.embedding.voyageai import VoyageAiEmbeddingDriver
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.structures import Agent
from griptape.tools import PromptSummaryTool, WebScraperTool

Defaults.drivers_config = DriversConfig(
    prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1"),
    embedding_driver=VoyageAiEmbeddingDriver(),
)

Defaults.drivers_config = DriversConfig(
    prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1"),
    embedding_driver=VoyageAiEmbeddingDriver(),
)

agent = Agent(
    tools=[WebScraperTool(off_prompt=True), PromptSummaryTool(off_prompt=False)],
)

agent.run("based on https://www.griptape.ai/, tell me what Griptape is")
```

Event Listener

Overview

Event Listener Drivers are used to send Gen AI Builder *Events* to external services.

You can instantiate Drivers and pass them to Event Listeners in your Structure:

```
import os

from griptape.drivers.event_listener.amazon_sqs import AmazonSqsEventListenerDriver
from griptape.events import EventBus, EventListener
from griptape.rules import Rule
from griptape.structures import Agent

EventBus.add_event_listeners(
    [
        EventListener(
            event_listener_driver=AmazonSqsEventListenerDriver(
                queue_url=os.environ["AMAZON_SQS_QUEUE_URL"],
            ),
        ),
    ]
)

agent = Agent(
    rules=[
        Rule(value="You will be provided with a block of text, and your task is to␣
↪extract a list of keywords from it.")
    ],
```

(continues on next page)

(continued from previous page)

```
)

agent.run(
    """Black-on-black ware is a 20th- and 21st-century pottery tradition developed by␣
↪the Puebloan Native American ceramic artists in Northern New Mexico.
    Traditional reduction-fired blackware has been made for centuries by pueblo␣
↪artists.
    Black-on-black ware of the past century is produced with a smooth surface, with␣
↪the designs applied through selective burnishing or the application of refractory␣
↪slip.
    Another style involves carving or incising designs and selectively polishing the␣
↪raised areas.
    For generations several families from Khapo Owingeh and Pohwhóge Owingeh pueblos␣
↪have been making black-on-black ware with the techniques passed down from matriarch␣
↪potters. Artists from other pueblos have also produced black-on-black ware.
    Several contemporary artists have created works honoring the pottery of their␣
↪ancestors."""
)
```

Or use them independently:

```
from griptape.artifacts import TextArtifact
from griptape.drivers.event_listener.griptape_cloud import␣
↪GriptapeCloudEventListenerDriver
from griptape.events import FinishStructureRunEvent

#  By default, GriptapeCloudEventListenerDriver uses the api key provided

#  in the GT_CLOUD_API_KEY environment variable.

event_driver = GriptapeCloudEventListenerDriver()

done_event = FinishStructureRunEvent(
    output_task_input=TextArtifact("Just started!"),
    output_task_output=TextArtifact("All done!"),
)

event_driver.publish_event(done_event)
```

Event Listener Drivers

Gen AI Builder offers the following Event Listener Drivers for forwarding Gen AI Builder Events.

Amazon SQS

The *AmazonSqsEventListenerDriver* sends Events to an Amazon SQS queue.

```
import os

from griptape.drivers.event_listener.amazon_sqs import AmazonSqsEventListenerDriver
from griptape.events import EventBus, EventListener
from griptape.rules import Rule
```

(continues on next page)

(continued from previous page)

```
from griptape.structures import Agent

EventBus.add_event_listeners(
    [
        EventListener(
            event_listener_driver=AmazonSqsEventListenerDriver(
                queue_url=os.environ["AMAZON_SQS_QUEUE_URL"],
            ),
        ),
    ]
)

agent = Agent(
    rules=[
        Rule(value="You will be provided with a block of text, and your task is to␣
↪extract a list of keywords from it.")
    ],
)

agent.run(
    """Black-on-black ware is a 20th- and 21st-century pottery tradition developed by␣
↪the Puebloan Native American ceramic artists in Northern New Mexico.
    Traditional reduction-fired blackware has been made for centuries by pueblo␣
↪artists.
    Black-on-black ware of the past century is produced with a smooth surface, with␣
↪the designs applied through selective burnishing or the application of refractory␣
↪slip.
    Another style involves carving or incising designs and selectively polishing the␣
↪raised areas.
    For generations several families from Khapo Owingeh and Pohwhóge Owingeh pueblos␣
↪have been making black-on-black ware with the techniques passed down from matriarch␣
↪potters. Artists from other pueblos have also produced black-on-black ware.
    Several contemporary artists have created works honoring the pottery of their␣
↪ancestors."""
)
```

AWS IoT

The *AwsIotCoreEventListenerDriver* sends Events to the AWS IoT Message Broker .

```
import os

from griptape.configs import Defaults
from griptape.configs.drivers import DriversConfig
from griptape.drivers.event_listener.aws_iot_core import AwsIotCoreEventListenerDriver
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.events import EventBus, EventListener, FinishStructureRunEvent
from griptape.rules import Rule
from griptape.structures import Agent

Defaults.drivers_config = DriversConfig(prompt_driver=OpenAiChatPromptDriver(model=
↪"gpt-3.5-turbo", temperature=0.7))
```

(continues on next page)

(continued from previous page)

```
EventBus.add_event_listeners(
    [
        EventListener(
            event_types=[FinishStructureRunEvent],
            event_listener_driver=AwsIotCoreEventListenerDriver(
                topic=os.environ["AWS_IOT_CORE_TOPIC"],
                iot_endpoint=os.environ["AWS_IOT_CORE_ENDPOINT"],
            ),
        ),
    ]
)

agent = Agent(
    rules=[Rule(value="You will be provided with a text, and your task is to extract␣
↪the airport codes from it.")],
)

agent.run("I want to fly from Orlando to Boston")
```

Gen AI Builder

The *GriptapeCloudEventListenerDriver* sends Events to Gen AI Builder .

Note

This Driver is required when using the Gen AI Builder Managed Structures feature. For local development, you can use the Skatepark Emulator .

```
from griptape.drivers.event_listener.griptape_cloud import␣
↪GriptapeCloudEventListenerDriver
from griptape.events import EventBus, EventListener, FinishStructureRunEvent
from griptape.structures import Agent

EventBus.add_event_listeners(
    [
        EventListener(
            event_types=[FinishStructureRunEvent],
            # By default, GriptapeCloudEventListenerDriver uses the api key provided
            # in the GT_CLOUD_API_KEY environment variable.
            event_listener_driver=GriptapeCloudEventListenerDriver(),
        ),
    ]
)

agent = Agent()
agent.run("Create a list of 8 questions for an interview with a science fiction␣
↪author.")
```

Webhook Event Listener Driver

The *WebhookEventListenerDriver* sends Events to any Webhook URL.

```
import os

from griptape.drivers.event_listener.webhook import WebhookEventListenerDriver
from griptape.events import EventBus, EventListener, FinishStructureRunEvent
from griptape.structures import Agent

EventBus.add_event_listeners(
    [
        EventListener(
            event_types=[FinishStructureRunEvent],
            event_listener_driver=WebhookEventListenerDriver(
                webhook_url=os.environ["WEBHOOK_URL"],
            ),
        ),
    ]
)

agent = Agent()

agent.run("Analyze the pros and cons of remote work vs. office work")
```

Pusher

The *PusherEventListenerDriver* sends Events to Pusher .

```
import os

from griptape.drivers.event_listener.pusher import PusherEventListenerDriver
from griptape.events import EventBus, EventListener, FinishStructureRunEvent
from griptape.structures import Agent

EventBus.add_event_listeners(
    [
        EventListener(
            event_types=[FinishStructureRunEvent],
            event_listener_driver=PusherEventListenerDriver(
                batched=False,
                app_id=os.environ["PUSHER_APP_ID"],
                key=os.environ["PUSHER_KEY"],
                secret=os.environ["PUSHER_SECRET"],
                cluster=os.environ["PUSHER_CLUSTER"],
                channel="my-channel",
                event_name="my-event",
            ),
        ),
    ],
)

agent = Agent()
```

(continues on next page)

(continued from previous page)

```
agent.run("Analyze the pros and cons of remote work vs. office work")
```

File Manager

Overview

File Manager Drivers can be used to load and save files with local or external file systems.

You can use File Manager Drivers with Loaders:

```
from griptape.drivers.file_manager.local import LocalFileManagerDriver
from griptape.loaders import TextLoader

local_file_manager_driver = LocalFileManagerDriver()

loader = TextLoader(file_manager_driver=local_file_manager_driver)
text_artifact = loader.load("tests/resources/test.txt")

print(text_artifact.value)
```

Or use them independently as shown below for each driver:

File Manager Drivers

Gen AI Builder

The *GriptapeCloudFileManagerDriver* allows you to load and save files sourced from Gen AI Builder Asset and Bucket resources.

```
import os

from griptape.drivers.file_manager.griptape_cloud import␣
↪GriptapeCloudFileManagerDriver

gtc_file_manager_driver = GriptapeCloudFileManagerDriver(
    api_key=os.environ["GT_CLOUD_API_KEY"],
    bucket_id=os.environ["GT_CLOUD_BUCKET_ID"],
)

#  Download File

file_contents = gtc_file_manager_driver.load_file(os.environ["GT_CLOUD_ASSET_NAME"])

print(file_contents)

#  Upload File

response = gtc_file_manager_driver.save_file(os.environ["GT_CLOUD_ASSET_NAME"], file_
↪contents.value)

print(response)
```

Local

The *LocalFileManagerDriver* allows you to load and save files sourced from a local directory.

```
from griptape.drivers.file_manager.local import LocalFileManagerDriver

local_file_manager_driver = LocalFileManagerDriver()

#  Download File

file_contents = local_file_manager_driver.load_file("tests/resources/test.txt")

print(file_contents)

#  Upload File

response = local_file_manager_driver.save_file("tests/resources/test.txt", file_
↪contents.value)

print(response)
```

Amazon S3

The *LocalFile ManagerDriver* allows you to load and save files sourced from an Amazon S3 bucket.

```
import os

import boto3

from griptape.drivers.file_manager.amazon_s3 import AmazonS3FileManagerDriver

amazon_s3_file_manager_driver = AmazonS3FileManagerDriver(
    bucket=os.environ["AMAZON_S3_BUCKET"],
    session=boto3.Session(
        region_name=os.environ["AWS_DEFAULT_REGION"],
        aws_access_key_id=os.environ["AWS_ACCESS_KEY_ID"],
        aws_secret_access_key=os.environ["AWS_SECRET_ACCESS_KEY"],
    ),
)

#  Download File

file_contents = amazon_s3_file_manager_driver.load_file(os.environ["AMAZON_S3_KEY"])

print(file_contents)

#  Upload File

response = amazon_s3_file_manager_driver.save_file(os.environ["AMAZON_S3_KEY"], file_
↪contents.value)

print(response)
```

Image Generation

Overview

Image Generation Drivers build and execute API calls to image generation models.

Provide a Driver to a *RAG Tool* for use by an *agent* :

```
from griptape.drivers.image_generation.openai import OpenAiImageGenerationDriver
from griptape.structures import Agent
from griptape.tools import PromptImageGenerationTool

driver = OpenAiImageGenerationDriver(
    model="gpt-image-1",
)

agent = Agent(
    tools=[
        PromptImageGenerationTool(image_generation_driver=driver),
    ]
)

agent.run("Generate a watercolor painting of a dog riding a skateboard")
```

Image Generation Drivers

Gen AI Builder

The *Gen AI Builder Image Generation Driver* provides access to image generation models hosted by Gen AI Builder.

Today, the only accessible model is `dall-e-3` .

```
import os
from io import BytesIO

from PIL import Image

from griptape.drivers.image_generation.griptape_cloud import␣
↪GriptapeCloudImageGenerationDriver

driver = GriptapeCloudImageGenerationDriver(
    api_key=os.environ["GT_CLOUD_API_KEY"],
    model="dall-e-3",
)

image = driver.run_text_to_image(["A capybara sitting on a rock in the sun."])

Image.open(BytesIO(image.value)).show()
```

Amazon Bedrock

The *Amazon Bedrock Image Generation Driver* provides multi-model access to image generation models hosted by Amazon Bedrock. This Driver manages API calls to the Bedrock API, while the specific Model Drivers below format the API requests and parse the responses.

Stable Diffusion

The *Bedrock Stable Diffusion Model Driver* provides support for Stable Diffusion models hosted by Amazon Bedrock. This Model Driver supports configurations specific to Stable Diffusion, like style presets, clip guidance presets, and sampler.

This Model Driver supports negative prompts. When provided, the image generation request will include negatively-weighted prompts describing features or characteristics to avoid in the resulting generation.

```
from griptape.drivers.image_generation.amazon_bedrock import␣
↪AmazonBedrockImageGenerationDriver
from griptape.drivers.image_generation_model.bedrock_stable_diffusion import (
    BedrockStableDiffusionImageGenerationModelDriver,
)
from griptape.structures import Agent
from griptape.tools import PromptImageGenerationTool

model_driver = BedrockStableDiffusionImageGenerationModelDriver(
    style_preset="pixel-art",
)

driver = AmazonBedrockImageGenerationDriver(
    image_generation_model_driver=model_driver,
    model="stability.stable-diffusion-xl-v1",
)

agent = Agent(
    tools=[
        PromptImageGenerationTool(image_generation_driver=driver),
    ]
)

agent.run("Generate an image of a dog riding a skateboard")
```

Titan

The *Bedrock Titan Image Generator Model Driver* provides support for Titan Image Generator models hosted by Amazon Bedrock. This Model Driver supports configurations specific to Titan Image Generator, like quality, seed, and cfg_scale.

This Model Driver supports negative prompts. When provided, the image generation request will include negatively-weighted prompts describing features or characteristics to avoid in the resulting generation.

```
from griptape.drivers.image_generation.amazon_bedrock import␣
↪AmazonBedrockImageGenerationDriver
from griptape.drivers.image_generation_model.bedrock_titan import␣
↪BedrockTitanImageGenerationModelDriver
from griptape.structures import Agent
from griptape.tools import PromptImageGenerationTool

model_driver = BedrockTitanImageGenerationModelDriver()

driver = AmazonBedrockImageGenerationDriver(
    image_generation_model_driver=model_driver,
```

(continues on next page)

(continued from previous page)

```
    model="amazon.titan-image-generator-v2:0",
)

agent = Agent(
    tools=[
        PromptImageGenerationTool(image_generation_driver=driver),
    ]
)

agent.run("Generate a watercolor painting of a dog riding a skateboard")
```

Azure OpenAI

The *Azure OpenAI Image Generation Driver* provides access to OpenAI models hosted by Azure. In addition to the configurations provided by the underlying OpenAI Driver, the Azure OpenAI Driver allows configuration of Azure-specific deployment values.

```
import os

from griptape.drivers.image_generation.openai import AzureOpenAiImageGenerationDriver
from griptape.structures import Agent
from griptape.tools import PromptImageGenerationTool

driver = AzureOpenAiImageGenerationDriver(
    model="dall-e-3",
    azure_endpoint=os.environ["AZURE_OPENAI_ENDPOINT_2"],
    api_key=os.environ["AZURE_OPENAI_API_KEY_2"],
)

agent = Agent(
    tools=[
        PromptImageGenerationTool(image_generation_driver=driver),
    ]
)

agent.run("Generate a watercolor painting of a dog riding a skateboard")
```

Leonardo.Ai

The *Leonardo Image Generation Driver* enables image generation using models hosted by Leonardo.ai .

This Driver supports configurations like model selection, image size, specifying a generation seed, and generation steps. For details on supported configuration parameters, see *Leonardo.Ai's image generation documentation* .

This Driver supports negative prompts. When provided, the image generation request will include negatively-weighted prompts describing features or characteristics to avoid in the resulting generation.

```
import os

from griptape.drivers.image_generation.leonardo import LeonardoImageGenerationDriver
from griptape.structures import Agent
from griptape.tools import PromptImageGenerationTool
```

(continues on next page)

(continued from previous page)

```
driver = LeonardoImageGenerationDriver(
    model=os.environ["LEONARDO_MODEL_ID"],
    api_key=os.environ["LEONARDO_API_KEY"],
    image_width=512,
    image_height=1024,
)

agent = Agent(
    tools=[
        PromptImageGenerationTool(image_generation_driver=driver),
    ]
)

agent.run("Generate a watercolor painting of a dog riding a skateboard")
```

OpenAI

The *OpenAI Image Generation Driver* provides access to OpenAI image generation models. Like other OpenAI Drivers, the image generation Driver will implicitly load an API key in the `OPENAI_API_KEY` environment variable if one is not explicitly provided.

This Driver supports image generation configurations like style presets, image quality preference, and image size. For details on supported configuration values, see the *OpenAI documentation* .

```
from griptape.drivers.image_generation.openai import OpenAiImageGenerationDriver
from griptape.structures import Agent
from griptape.tools import FileManagerTool, PromptImageGenerationTool

driver = OpenAiImageGenerationDriver(model="gpt-image-1")

agent = Agent(tools=[PromptImageGenerationTool(image_generation_driver=driver, off_
↪prompt=True), FileManagerTool()])

agent.run("Generate a watercolor painting of a dog riding a skateboard and save it to␣
↪dog.png")
```

HuggingFace Pipelines

The *HuggingFace Pipelines Image Generation Driver* enables image generation through locally-hosted models using the HuggingFace *Diffusers* library. This Driver requires a *Stable Diffusion 3 Image Generation Pipeline Driver* to prepare the appropriate Pipeline.

This Driver requires a `model` configuration, specifying the model to use for image generation. The value of the `model` configuration must be one of the following:

- A model name from the HuggingFace Model Hub, like `stabilityai/stable-diffusion-3-medium-diffusers`
- A path to the directory containing a model on the filesystem, like `./models/stable-diffusion-3/`
- A path to a file containing a model on the filesystem, like `./models/sd3_medium_incl_clips.safetensors`

The `device` configuration specifies the hardware device used to run inference. Common values include `cuda` (supporting CUDA-enabled GPUs), `cpu` (supported by a device's CPU), and `mps` (supported by Apple silicon GPUs). For more information, see HuggingFace's documentation on GPU inference.

Stable Diffusion 3 Image Generation Pipeline Driver

The *Stable Diffusion 3 Image Generation Pipeline Driver* provides a Stable `Diffusion3DiffusionPipeline` for text-to-image generations via the *HuggingFace Pipelines Image Generation Driver's* `.try_text_to_image()` method. This Driver accepts a text prompt and configurations including Stable Diffusion 3 model, output image size, generation seed, and inference steps.

Image generation consumes substantial memory. On devices with limited VRAM, it may be necessary to enable the `enable_model_cpu_offload` or `drop_t5_encoder` configurations. For more information, see HuggingFace's documentation on reduced memory usage.

```
from griptape.artifacts import TextArtifact
from griptape.drivers.image_generation.huggingface_pipeline import␣
↪HuggingFacePipelineImageGenerationDriver
from griptape.drivers.image_generation_pipeline.stable_diffusion_3 import␣
↪StableDiffusion3ImageGenerationPipelineDriver
from griptape.structures import Pipeline
from griptape.tasks import PromptImageGenerationTask

image_generation_task = PromptImageGenerationTask(
    input=TextArtifact("landscape photograph, verdant, countryside, 8k"),
    image_generation_driver=HuggingFacePipelineImageGenerationDriver(
        model="stabilityai/stable-diffusion-3-medium-diffusers",
        device="cuda",
        pipeline_driver=StableDiffusion3ImageGenerationPipelineDriver(
            height=512,
            width=512,
        ),
    ),
)

output_artifact = Pipeline(tasks=[image_generation_task]).run().output
```

Stable Diffusion 3 Img2Img Image Generation Pipeline Driver

The *Stable Diffusion 3 Img2Img Image Generation Pipeline Driver* provides a `StableDiffusion3Img2Img-Pipeline` for image-to-image generations, accepting a text prompt and input image. This Driver accepts a text prompt, an input image, and configurations including Stable Diffusion 3 model, output image size, inference steps, generation seed, and strength of generation over the input image.

```
from griptape.artifacts import TextArtifact
from griptape.drivers.image_generation.huggingface_pipeline import␣
↪HuggingFacePipelineImageGenerationDriver
from griptape.drivers.image_generation_pipeline.stable_diffusion_3_img_2_img import (
    StableDiffusion3Img2ImgImageGenerationPipelineDriver,
)
from griptape.loaders import ImageLoader
from griptape.structures import Pipeline
from griptape.tasks import VariationImageGenerationTask
```

(continues on next page)

(continued from previous page)

```
prompt_artifact = TextArtifact("landscape photograph, verdant, countryside, 8k")
input_image_artifact = ImageLoader().load("tests/resources/mountain.png")

image_variation_task = VariationImageGenerationTask(
    input=(prompt_artifact, input_image_artifact),
    image_generation_driver=HuggingFacePipelineImageGenerationDriver(
        model="stabilityai/stable-diffusion-3-medium-diffusers",
        device="cuda",
        pipeline_driver=StableDiffusion3Img2ImgImageGenerationPipelineDriver(
            height=1024,
            width=1024,
        ),
    ),
)

output_artifact = Pipeline(tasks=[image_variation_task]).run().output
```

StableDiffusion3ControlNetImageGenerationPipelineDriver

Note

The *Stable Diffusion 3 Image Generation Pipeline Driver* requires the *drivers-image-generation-huggingface* extra.

The *StableDiffusion3ControlNetImageGenerationPipelineDriver* provides a `StableDiffusion3ControlNetPipeline` for image-to-image generations, accepting a text prompt and a control image. This Driver accepts a text prompt, a control image, and configurations including Stable Diffusion 3 model, ControlNet model, output image size, generation seed, inference steps, and the degree to which the model adheres to the control image.

```
from griptape.artifacts import TextArtifact
from griptape.drivers.image_generation.huggingface_pipeline import␣
↪HuggingFacePipelineImageGenerationDriver
from griptape.drivers.image_generation_pipeline.stable_diffusion_3_controlnet import (
    StableDiffusion3ControlNetImageGenerationPipelineDriver,
)
from griptape.loaders import ImageLoader
from griptape.structures import Pipeline
from griptape.tasks import VariationImageGenerationTask

prompt_artifact = TextArtifact("landscape photograph, verdant, countryside, 8k")
control_image_artifact = ImageLoader().load("canny_control_image.png")

controlnet_task = VariationImageGenerationTask(
    input=(prompt_artifact, control_image_artifact),
    image_generation_driver=HuggingFacePipelineImageGenerationDriver(
        model="stabilityai/stable-diffusion-3-medium-diffusers",
        device="cuda",
        pipeline_driver=StableDiffusion3ControlNetImageGenerationPipelineDriver(
            controlnet_model="InstantX/SD3-Controlnet-Canny",
            height=768,
            width=1024,
```

(continues on next page)

(continued from previous page)

```
        ),
    ),
)

output_artifact = Pipeline(tasks=[controlnet_task]).run().output
```

Observability

Overview

Observability Drivers are used by *Observability* to send telemetry (metrics and traces) related to the execution of an LLM application. The telemetry can be used to monitor the application and to diagnose and troubleshoot issues. All Observability Drivers implement the following methods:

- `__enter__()` sets up the Driver.
- `__exit__()` tears down the Driver.
- `observe()` wraps all functions and methods marked with the `@observable` decorator. At a bare minimum, implementations call the wrapped function and return its result (a no-op). This enables the Driver to generate telemetry related to the invocation's call arguments, return values, exceptions, latency, etc.

Observability Drivers

Gen AI Builder

The Gen AI Builder Observability Driver instruments `@observable` functions and methods with metrics and traces for use with the Gen AI Builder.

> **Note**
>
> For the Gen AI Builder Observability Driver to function as intended, it must be run from within either a Managed Structure on Gen AI Builder or locally via the Skatepark Emulator .

Here is an example of how to use the `GriptapeCloudObservabilityDriver` with the `Observability` context manager to send the telemetry to Gen AI Builder:

```
from griptape.drivers.observability.griptape_cloud import␣
↪GriptapeCloudObservabilityDriver
from griptape.observability import Observability
from griptape.rules import Rule
from griptape.structures import Agent

observability_driver = GriptapeCloudObservabilityDriver()

with Observability(observability_driver=observability_driver):
    agent = Agent(rules=[Rule("Output one word")])
    agent.run("Name an animal")
```

OpenTelemetry

The OpenTelemetry Observability Driver instruments `@observable` functions and methods with metrics and traces for use with OpenTelemetry. You must configure a destination for the telemetry by providing a `SpanProcessor` to the Driver.

Here is an example of how to use the `OpenTelemetryObservabilityDriver` with the `Observability` context manager to output the telemetry directly to the console:

```
from opentelemetry.sdk.trace.export import BatchSpanProcessor, ConsoleSpanExporter

from griptape.drivers.observability.open_telemetry import␣
↪OpenTelemetryObservabilityDriver
from griptape.observability import Observability
from griptape.rules import Rule
from griptape.structures import Agent

observability_driver = OpenTelemetryObservabilityDriver(
    service_name="name-an-animal", span_
↪processor=BatchSpanProcessor(ConsoleSpanExporter())
)

with Observability(observability_driver=observability_driver):
    agent = Agent(rules=[Rule("Output one word")])
    agent.run("Name an animal")
```

Rerank

Overview

Rerank Drivers can be used to rerank search results for a particular query. Every Rerank Driver implements the following methods that can be used directly:

- `run(query: str, artifacts: list *TextArtifact* based on the original query.

Rerank Drivers can also be used with a RagEngine's Rerank Module .

Rerank Drivers

Local

The *LocalRerankDriver* uses a simple relatedness calculation.

```
from griptape.artifacts import TextArtifact
from griptape.drivers.rerank.local import LocalRerankDriver

rerank_driver = LocalRerankDriver()

artifacts = rerank_driver.run(
    "What is the capital of France?",
    [
        TextArtifact("Hotdog"),
        TextArtifact("San Francisco"),
        TextArtifact("Paris"),
        TextArtifact("Baguette"),
```

(continues on next page)

(continued from previous page)

```
        TextArtifact("French Hotdog"),
    ],
)
for artifact in artifacts:
    print(artifact.value)
```

Cohere

The *CohereRerankDriver* uses *Cohere's Rerank* model.

```
import os

from griptape.artifacts import TextArtifact
from griptape.drivers.rerank.cohere import CohereRerankDriver

rerank_driver = CohereRerankDriver(
    api_key=os.environ["COHERE_API_KEY"],
)

artifacts = rerank_driver.run(
    "Where is NYC located?",
    [
        TextArtifact("NYC Media"),
        TextArtifact("New York City Police Department"),
        TextArtifact("New York City"),
        TextArtifact("New York City Subway"),
    ],
)
for artifact in artifacts:
    print(artifact.value)
```

Nvidia NIM

The *NvidiaNimRerankDriver* uses the *Nvidia NIM Reranking API* .

```
from griptape.artifacts import TextArtifact
from griptape.drivers.rerank.nvidia_nim import NvidiaNimRerankDriver

rerank_driver = NvidiaNimRerankDriver(
    model="nvidia/bert-base-uncased",
    base_url="http://localhost:8000",
)

artifacts = rerank_driver.run(
    "Where is NYC located?",
    [
        TextArtifact("NYC Media"),
        TextArtifact("New York City Police Department"),
        TextArtifact("New York City"),
        TextArtifact("New York City Subway"),
    ],
```

(continues on next page)

(continued from previous page)

```
)
for artifact in artifacts:
    print(artifact.value)
```

Ruleset

Overview

Ruleset Drivers can be used to load rules in from external sources.

Ruleset Drivers

Local

The *LocalRulesetDriver* allows you to load a Ruleset from a local JSON file. The `persist_dir` parameter is used to specify a local directory where one or more Ruleset files are located. If no `persist_dir` parameter is given, the `.load` method is a no-op.

```
import json
import os
from pathlib import Path

from griptape.drivers.ruleset.local import LocalRulesetDriver
from griptape.rules import Ruleset

ruleset_dir = "path/to/ruleset/dir"
ruleset_name = "my_local_ruleset.json"
ruleset_path = Path(os.path.join(ruleset_dir, ruleset_name))

os.makedirs(ruleset_dir, exist_ok=True)

ruleset_path.write_text(json.dumps({"rules": [{"value": "Always talk like a pirate."}
↪]}))

ruleset = Ruleset(
    name=ruleset_name,
    ruleset_driver=LocalRulesetDriver(persist_dir=ruleset_dir),
)
```

Gen AI Builder

The *GriptapeCloudRulesetDriver* allows you to load a Gen AI Builder Ruleset resource. `Ruleset.name` is used to try and find a Gen AI Builder Ruleset with that alias.

```
from griptape.drivers.ruleset.griptape_cloud import GriptapeCloudRulesetDriver
from griptape.rules import Ruleset

rulset = Ruleset(
    name="my_griptape_cloud_ruleset_alias",
    ruleset_driver=GriptapeCloudRulesetDriver(),
)
```

SQL

Overview

SQL drivers can be used to make SQL queries and load table schemas. They are used by the *SqlLoader* to process data. All loaders implement the following methods:

- `execute_query()` executes a query and returns *RowResultdataclass* s.
- `execute_query_row()` executes a query and returns a raw result from SQL.
- `get_table_schema()` returns a table schema.

SQL Drivers

SQL

Note that you may need to install the appropriate database driver for your SQL database. For example, to use the `psycopg2` driver for PostgreSQL, you can install it with `pip install psycopg2-binary`.

This is a basic SQL loader based on SQLAlchemy 2.0 . Here is an example of how to use it:

```
from griptape.drivers.sql.sql_driver import SqlDriver

driver = SqlDriver(engine_url="sqlite:///:memory:")

driver.execute_query("select foo, bar;")
```

Amazon Redshift

This is a SQL driver for interacting with the Amazon Redshift Data API

to execute statements. Here is an example of how to use it for Redshift Serverless:

```
import os

import boto3

from griptape.drivers.sql.amazon_redshift import AmazonRedshiftSqlDriver

session = boto3.Session()

driver = AmazonRedshiftSqlDriver(
    database=os.environ["REDSHIFT_DATABASE"],
    session=session,
    cluster_identifier=os.environ["REDSHIFT_CLUSTER_IDENTIFIER"],
)

driver.execute_query("select * from people;")
```

Snowflake

This is a SQL driver based on the *Snowflake SQLAlchemy Toolkit* which runs on top of the Snowflake Connector for Python. Here is an example of how to use it:

```
import os

import snowflake.connector
from snowflake.connector import SnowflakeConnection

from griptape.drivers.sql.snowflake import SnowflakeSqlDriver

def get_snowflake_connection() -> SnowflakeConnection:
    return snowflake.connector.connect(
        account=os.environ["SNOWFLAKE_ACCOUNT"],
        user=os.environ["SNOWFLAKE_USER"],
        password=os.environ["SNOWFLAKE_PASSWORD"],
        database=os.environ["SNOWFLAKE_DATABASE"],
        schema=os.environ["SNOWFLAKE_SCHEMA"],
        warehouse=os.environ["SNOWFLAKE_WAREHOUSE"],
    )

driver = SnowflakeSqlDriver(get_connection=get_snowflake_connection)

driver.execute_query("select * from people;")
```

Structure Run

Overview

Structure Run Drivers can be used to run Gen AI Builder Structures in a variety of runtime environments. When combined with the *Structure Run Task* or *Structure Run Tool* you can create complex, multi-agent pipelines that span multiple runtime environments.

Structure Run Drivers

Local

The *LocalStructureRunDriver* is used to run Gen AI Builder Structures in the same runtime environment as the code that is running the Structure.

```
from griptape.drivers.structure_run.local import LocalStructureRunDriver
from griptape.rules import Rule
from griptape.structures import Agent, Pipeline
from griptape.tasks import StructureRunTask

def build_joke_teller() -> Agent:
    return Agent(
        rules=[
            Rule(
                value="You are very funny.",
            )
        ],
    )

def build_joke_rewriter() -> Agent:
    return Agent(
        rules=[
```

(continues on next page)

(continued from previous page)

```
            Rule(
                value="You are the editor of a joke book. But you only speak in␣
↪riddles",
            )
        ],
    )

joke_coordinator = Pipeline(
    tasks=[
        StructureRunTask(
            structure_run_driver=LocalStructureRunDriver(
                create_structure=build_joke_teller,
            ),
        ),
        StructureRunTask(
            ("Rewrite this joke: {{ parent_output }}",),
            structure_run_driver=LocalStructureRunDriver(
                create_structure=build_joke_rewriter,
            ),
        ),
    ]
)

joke_coordinator.run("Tell me a joke")
```

Gen AI Builder

The *GriptapeCloudStructureRunDriver* is used to run Gen AI Builder Structures in the Gen AI Builder.

```
import os

from griptape.drivers.structure_run.griptape_cloud import␣
↪GriptapeCloudStructureRunDriver
from griptape.drivers.structure_run.local import LocalStructureRunDriver
from griptape.rules import Rule
from griptape.structures import Agent, Pipeline
from griptape.tasks import StructureRunTask

base_url = os.environ["GT_CLOUD_BASE_URL"]
api_key = os.environ["GT_CLOUD_API_KEY"]
structure_id = os.environ["GT_CLOUD_STRUCTURE_ID"]

pipeline = Pipeline(
    tasks=[
        StructureRunTask(
            ("Think of a question related to Retrieval Augmented Generation.",),
            structure_run_driver=LocalStructureRunDriver(
                create_structure=lambda: Agent(
                    rules=[
                        Rule(
                            value="You are an expert in Retrieval Augmented␣
↪Generation.",
```

(continues on next page)

(continued from previous page)

```
                        ),
                        Rule(
                            value="Only output your answer, no other information.",
                        ),
                    ]
                )
            ),
        ),
        StructureRunTask(
            ("{{ parent_output }}",),
            structure_run_driver=GriptapeCloudStructureRunDriver(
                base_url=base_url,
                api_key=api_key,
                structure_id=structure_id,
            ),
        ),
    ]
)

pipeline.run()
```

Text to Speech

Overview

Text to Speech Drivers are used to build and execute API calls to audio generation models.

Provide a Driver to a *RAG Tool* for use by an *agent* :

Text to Speech Drivers

Eleven Labs

The *Eleven Labs Text to Speech Driver* provides support for text-to-speech models hosted by Eleven Labs. This Driver supports configurations specific to Eleven Labs, like voice selection and output format.

```
import os

from griptape.drivers.text_to_speech.elevenlabs import ElevenLabsTextToSpeechDriver
from griptape.structures import Agent
from griptape.tools.text_to_speech.tool import TextToSpeechTool

driver = ElevenLabsTextToSpeechDriver(
    api_key=os.environ["ELEVEN_LABS_API_KEY"],
    model="eleven_multilingual_v2",
    voice="Matilda",
)

tool = TextToSpeechTool(
    text_to_speech_driver=driver,
)

Agent(tools=[tool]).run("Generate audio from this text: Hello, world!")
```

OpenAI

The *OpenAI Text to Speech Driver* provides support for text-to-speech models hosted by OpenAI. This Driver supports configurations specific to OpenAI, like voice selection and output format.

```
from griptape.drivers.text_to_speech.openai import OpenAiTextToSpeechDriver
from griptape.structures import Agent
from griptape.tools.text_to_speech.tool import TextToSpeechTool

driver = OpenAiTextToSpeechDriver()

tool = TextToSpeechTool(
    text_to_speech_driver=driver,
)

Agent(tools=[tool]).run("Generate audio from this text: Hello, world!")
```

Azure OpenAI

The *Azure OpenAI Text to Speech Driver* provides support for text-to-speech models hosted in your Azure OpenAI instance. This Driver supports configurations specific to OpenAI, like voice selection and output format.

```
import os

from griptape.drivers.text_to_speech.openai import AzureOpenAiTextToSpeechDriver
from griptape.structures import Agent
from griptape.tools.text_to_speech.tool import TextToSpeechTool

driver = AzureOpenAiTextToSpeechDriver(
    api_key=os.environ["AZURE_OPENAI_API_KEY_4"],
    model="tts",
    azure_endpoint=os.environ["AZURE_OPENAI_ENDPOINT_4"],
)

tool = TextToSpeechTool(
    text_to_speech_driver=driver,
)

Agent(tools=[tool]).run("Generate audio from this text: Hello, world!")
```

Vector Store

Overview

Gen AI Builder provides a way to build drivers for vector DBs where embeddings can be stored and queried. Every Vector Store Driver implements the following methods:

- `upsert()` for updating or inserting new text, *TextArtifact* s or *ImageArtifact* s into vector DBs. The method will automatically generate embeddings for a given value.
- `upsert_collection()` for performing an `upsert()` in parallel.
- `upsert_vector()` for updating new vectors directly.
- `query()` for querying vector DBs.

Each Vector Store Driver takes a *BaseEmbeddingDriver* used to dynamically generate embeddings for strings.

Vector Store Drivers

Local

The *LocalVectorStoreDriver* can be used to load and query data from memory. Here is a complete example of how the Driver can be used to load a webpage into the Driver and query it later:

```
import os

from griptape.chunkers import TextChunker
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver
from griptape.drivers.vector.local import LocalVectorStoreDriver
from griptape.loaders import WebLoader

#  Initialize an Embedding Driver

embedding_driver = OpenAiEmbeddingDriver(api_key=os.environ["OPENAI_API_KEY"])

vector_store_driver = LocalVectorStoreDriver(embedding_driver=embedding_driver)

#  Load Artifacts from the web

artifact = WebLoader().load("https://www.griptape.ai")
chunks = TextChunker(max_tokens=100).chunk(artifact)

#  Upsert Artifacts into the Vector Store Driver

vector_store_driver.upsert_collection({"griptape": chunks})

results = vector_store_driver.query(query="What is griptape?")

values = [r.to_artifact().value for r in results]

print("\n\n".join(values))
```

Gen AI Builder Knowledge Base

The *GriptapeCloudVectorStoreDriver* can be used to query data from a Gen AI Builder Knowledge Base. Loading into Knowledge Bases is not supported at this time, only querying. Here is a complete example of how the Driver can be used to query an existing Knowledge Base:

```
import os

from griptape.drivers.vector.griptape_cloud import GriptapeCloudVectorStoreDriver

#  Initialize environment variables

gt_cloud_api_key = os.environ["GT_CLOUD_API_KEY"]
gt_cloud_knowledge_base_id = os.environ["GT_CLOUD_KB_ID"]

vector_store_driver = GriptapeCloudVectorStoreDriver(
```

(continues on next page)

(continued from previous page)

```
    api_key=gt_cloud_api_key, knowledge_base_id=gt_cloud_knowledge_base_id
)

results = vector_store_driver.query(query="What is griptape?")

values = [r.to_artifact().value for r in results]

print("\n\n".join(values))
```

Pinecone

The *PineconeVectorStoreDriver* supports the *Pinecone vector database* .

Here is an example of how the Driver can be used to load and query information in a Pinecone cluster:

```
import os

from griptape.chunkers import TextChunker
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver
from griptape.drivers.vector.pinecone import PineconeVectorStoreDriver
from griptape.loaders import WebLoader

NAMESPACE = "griptape"

#  Initialize an Embedding Driver

embedding_driver = OpenAiEmbeddingDriver(api_key=os.environ["OPENAI_API_KEY"])

vector_store_driver = PineconeVectorStoreDriver(
    api_key=os.environ["PINECONE_API_KEY"],
    environment=os.environ["PINECONE_ENVIRONMENT"],
    index_name=os.environ["PINECONE_INDEX_NAME"],
    embedding_driver=embedding_driver,
)

#  Load Artifacts from the web

artifact = WebLoader().load("https://www.griptape.ai")
chunks = TextChunker(max_tokens=100).chunk(artifact)

#  Upsert Artifacts into the Vector Store Driver

vector_store_driver.upsert_collection({NAMESPACE: chunks})

results = vector_store_driver.query(query="What is griptape?", namespace=NAMESPACE)

values = [r.to_artifact().value for r in results]

print("\n\n".join(values))
```

Marqo

The *MarqoVectorStoreDriver* supports the Marqo vector database.

Here is an example of how the Driver can be used to load and query information in a Marqo cluster:

```
import os

from griptape.chunkers import TextChunker
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.drivers.vector.marqo import MarqoVectorStoreDriver
from griptape.loaders import WebLoader

#  Initialize an Embedding Driver

embedding_driver = OpenAiEmbeddingDriver(api_key=os.environ["OPENAI_API_KEY"])
prompt_driver = OpenAiChatPromptDriver(model="gpt-3.5-turbo")

#  Define the namespace

namespace = "griptape-ai"

#  Initialize the Vector Store Driver

vector_store_driver = MarqoVectorStoreDriver(
    api_key=os.environ["MARQO_API_KEY"],
    url=os.environ["MARQO_URL"],
    index=os.environ["MARQO_INDEX_NAME"],
    embedding_driver=embedding_driver,
)

#  Load Artifacts from the web

artifact = WebLoader().load("https://www.griptape.ai")
chunks = TextChunker(max_tokens=200).chunk(artifact)

#  Upsert Artifacts into the Vector Store Driver

vector_store_driver.upsert_collection(
    {
        "griptape": chunks,
    }
)

results = vector_store_driver.query(query="What is griptape?")

values = [r.to_artifact().value for r in results]

print("\n\n".join(values))
```

Mongodb Atlas

The *MongoDbAtlasVectorStoreDriver* provides support for storing vector data in a MongoDB Atlas database.

Here is an example of how the Driver can be used to load and query information in a MongoDb Atlas Cluster:

```
import os

from griptape.chunkers import TextChunker
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver
from griptape.drivers.vector.mongodb_atlas import MongoDbAtlasVectorStoreDriver
from griptape.loaders import WebLoader

#  Initialize an Embedding Driver

embedding_driver = OpenAiEmbeddingDriver(api_key=os.environ["OPENAI_API_KEY"])

host = os.environ["MONGODB_HOST"]
username = os.environ["MONGODB_USERNAME"]
password = os.environ["MONGODB_PASSWORD"]
database_name = os.environ["MONGODB_DATABASE_NAME"]
collection_name = os.environ["MONGODB_COLLECTION_NAME"]
index_name = os.environ["MONGODB_INDEX_NAME"]
vector_path = os.environ["MONGODB_VECTOR_PATH"]

#  Initialize the Vector Store Driver

vector_store_driver = MongoDbAtlasVectorStoreDriver(
    connection_string=f"mongodb+srv://{username}:{password}@{host}/{database_name}",
    database_name=database_name,
    collection_name=collection_name,
    embedding_driver=embedding_driver,
    index_name=index_name,
    vector_path=vector_path,
)

#  Load Artifacts from the web

artifact = WebLoader().load("https://www.griptape.ai")
chunks = TextChunker(max_tokens=200).chunk(artifact)

#  Upsert Artifacts into the Vector Store Driver

vector_store_driver.upsert_collection({"griptape": chunks})

results = vector_store_driver.query(query="What is griptape?")

values = [r.to_artifact().value for r in results]

print("\n\n".join(values))
```

The format for creating a vector index should look similar to the following:

```
{
```

(continues on next page)

(continued from previous page)

```
  "fields": [
    {
      "numDimensions": 1536,
      "path": "<path_to_vector>",
      "similarity": "euclidean",
      "type": "vector"
    },
    {
      "path": "namespace",
      "type": "filter"
    }
  ]
}
```

Replace `path_to_vector` with the expected field name where the vector content will be.

Azure MongoDB

The *AzureMongoDbVectorStoreDriver* provides support for storing vector data in an Azure CosmosDb database account using the MongoDb vCore API

Here is an example of how the Driver can be used to load and query information in an Azure CosmosDb MongoDb vCore database. It is very similar to the Driver for *Mongodb Atlas* :

```
import os

from griptape.chunkers import TextChunker
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver
from griptape.drivers.vector.azure_mongodb import AzureMongoDbVectorStoreDriver
from griptape.loaders import WebLoader

#  Initialize an Embedding Driver

embedding_driver = OpenAiEmbeddingDriver(api_key=os.environ["OPENAI_API_KEY"])

azure_host = os.environ["AZURE_MONGODB_HOST"]
username = os.environ["AZURE_MONGODB_USERNAME"]
password = os.environ["AZURE_MONGODB_PASSWORD"]
database_name = os.environ["AZURE_MONGODB_DATABASE_NAME"]
collection_name = os.environ["AZURE_MONGODB_COLLECTION_NAME"]
index_name = os.environ["AZURE_MONGODB_INDEX_NAME"]
vector_path = os.environ["AZURE_MONGODB_VECTOR_PATH"]

#  Initialize the Vector Store Driver

vector_store_driver = AzureMongoDbVectorStoreDriver(
    connection_string=f"mongodb+srv://{username}:{password}@{azure_host}/{database_
↪name}?tls=true&authMechanism=SCRAM-SHA-256&retrywrites=false&maxIdleTimeMS=120000",
    database_name=database_name,
    collection_name=collection_name,
    embedding_driver=embedding_driver,
    index_name=index_name,
    vector_path=vector_path,
```

(continues on next page)

(continued from previous page)

```
)

#  Load Artifacts from the web

artifact = WebLoader().load("https://www.griptape.ai")
chunks = TextChunker(max_tokens=200).chunk(artifact)

#  Upsert Artifacts into the Vector Store Driver

vector_store_driver.upsert_collection(
    {
        "griptape": chunks,
    }
)

results = vector_store_driver.query(query="What is griptape?")

values = [r.to_artifact().value for r in results]

print("\n\n".join(values))
```

Redis

The *RedisVectorStoreDriver* integrates with the Redis vector storage system.

Here is an example of how the Driver can be used to load and query information in a Redis Cluster:

```
import os

from griptape.chunkers import TextChunker
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver
from griptape.drivers.vector.redis import RedisVectorStoreDriver
from griptape.loaders import WebLoader

#  Initialize an Embedding Driver

embedding_driver = OpenAiEmbeddingDriver(api_key=os.environ["OPENAI_API_KEY"])

vector_store_driver = RedisVectorStoreDriver(
    host=os.environ["REDIS_HOST"],
    port=int(os.environ["REDIS_PORT"]),
    username=os.environ["REDIS_USERNAME"],
    password=os.environ["REDIS_PASSWORD"],
    index=os.environ["REDIS_INDEX"],
    embedding_driver=embedding_driver,
)

#  Load Artifacts from the web

artifact = WebLoader().load("https://www.griptape.ai")
chunks = TextChunker(max_tokens=200).chunk(artifact)
```

(continues on next page)

(continued from previous page)

```
#  Upsert Artifacts into the Vector Store Driver

vector_store_driver.upsert_collection(
    {
        "griptape": chunks,
    }
)

results = vector_store_driver.query(query="What is griptape?")

values = [r.to_artifact().value for r in results]

print("\n\n".join(values))
```

The format for creating a vector index should be similar to the following:

```
FT.CREATE idx:griptape ON hash PREFIX 1 "griptape:" SCHEMA namespace TAG vector␣
↪VECTOR FLAT 6 TYPE FLOAT32 DIM 1536 DISTANCE_METRIC COSINE
```

OpenSearch

The *AmazonOpenSearchVectorStoreDriver* integrates with the OpenSearch platform, allowing for storage, retrieval, and querying of vector data.

Here is an example of how the Driver can be used to load and query information in an OpenSearch Cluster:

```
import os

import boto3

from griptape.chunkers import TextChunker
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver
from griptape.drivers.vector.amazon_opensearch import␣
↪AmazonOpenSearchVectorStoreDriver
from griptape.loaders import WebLoader

#  Initialize an Embedding Driver

embedding_driver = OpenAiEmbeddingDriver(api_key=os.environ["OPENAI_API_KEY"])

vector_store_driver = AmazonOpenSearchVectorStoreDriver(
    host=os.environ["AMAZON_OPENSEARCH_HOST"],
    index_name=os.environ["AMAZON_OPENSEARCH_INDEX_NAME"],
    session=boto3.Session(),
    embedding_driver=embedding_driver,
)

#  Load Artifacts from the web

artifact = WebLoader().load("https://www.griptape.ai")
chunks = TextChunker(max_tokens=200).chunk(artifact)
```

(continues on next page)

(continued from previous page)

```
#  Upsert Artifacts into the Vector Store Driver

vector_store_driver.upsert_collection(
    {
        "griptape": chunks,
    }
)

results = vector_store_driver.query(query="What is griptape?")

values = [r.to_artifact().value for r in results]

print("\n\n".join(values))
```

The body mappings for creating a vector index should look similar to the following:

```
{
    "mappings": {
        "properties": {
            "vector": {"type": "knn_vector", "dimension": 1536},
            "namespace": {"type": "keyword"},
            "metadata": {"type": "object", "enabled": true}
        }
    }
}
```

PGVector

The *PgVectorVectorStoreDriver* integrates with PGVector, a vector storage and search extension for Postgres. While Gen AI Builder will handle enabling the extension, PGVector must be installed and ready for use in your Postgres instance before using this Vector Store Driver.

Here is an example of how the Driver can be used to load and query information in a Postgres database:

```
import os

from griptape.chunkers import TextChunker
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver
from griptape.drivers.vector.pgvector import PgVectorVectorStoreDriver
from griptape.loaders import WebLoader

#  Initialize an Embedding Driver.

embedding_driver = OpenAiEmbeddingDriver(api_key=os.environ["OPENAI_API_KEY"])

db_user = os.environ["POSTGRES_USER"]
db_pass = os.environ["POSTGRES_PASSWORD"]
db_host = os.environ["POSTGRES_HOST"]
db_port = os.environ["POSTGRES_PORT"]
db_name = os.environ["POSTGRES_DB"]
db_connection_string = f"postgresql://{db_user}:{db_pass}@{db_host}:{db_port}/{db_
↪name}"
```

(continues on next page)

(continued from previous page)

```
vector_store_driver = PgVectorVectorStoreDriver(
    connection_string=db_connection_string,
    embedding_driver=embedding_driver,
    table_name="griptape_vectors",
)

#  Install required Postgres extensions and create database schema.

vector_store_driver.setup()

#  Load Artifacts from the web

artifact = WebLoader().load("https://www.griptape.ai")
chunks = TextChunker().chunk(artifact)

#  Upsert Artifacts into the Vector Store Driver

vector_store_driver.upsert_collection(
    {
        "griptape": chunks,
    }
)

results = vector_store_driver.query(query="What is griptape?")

values = [r.to_artifact().value for r in results]

print("\n\n".join(values))
```

Qdrant

The QdrantVectorStoreDriver supports the *Qdrant vector database* .

Here is an example of how the Driver can be used to query information in a Qdrant collection:

```
import os

from qdrant_client.http.models import Distance, VectorParams

from griptape.chunkers import TextChunker
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver
from griptape.drivers.vector.qdrant import QdrantVectorStoreDriver
from griptape.loaders import WebLoader

#  Set up environment variables

host = os.environ["QDRANT_CLUSTER_ENDPOINT"]
api_key = os.environ["QDRANT_CLUSTER_API_KEY"]

#  Initialize an Embedding Driver.

embedding_driver = OpenAiEmbeddingDriver(api_key=os.environ["OPENAI_API_KEY"])
```

(continues on next page)

(continued from previous page)

```
vector_store_driver = QdrantVectorStoreDriver(
    url=host,
    collection_name="griptape",
    content_payload_key="content",
    embedding_driver=embedding_driver,
    api_key=api_key,
)

#  Load Artifacts from the web

artifact = WebLoader().load("https://www.griptape.ai")
chunks = TextChunker(max_tokens=100).chunk(artifact)

#  Recreate Qdrant collection

vector_store_driver.client.recreate_collection(
    collection_name=vector_store_driver.collection_name,
    vectors_config=VectorParams(size=1536, distance=Distance.COSINE),
)

#  Upsert Artifacts into the Vector Store Driver

vector_store_driver.upsert_collection({"griptape": chunks})

results = vector_store_driver.query(query="What is griptape?")

values = [r.to_artifact().value for r in results]

print("\n\n".join(values))
```

Astra DB

The AstraDbVectorStoreDriver supports DataStax Astra DB .

The following example shows how to store vector entries and query the information using the driver:

```
import os

from griptape.chunkers import TextChunker
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver
from griptape.drivers.vector.astradb import AstraDbVectorStoreDriver
from griptape.loaders import WebLoader

#  Astra DB secrets and connection parameters

api_endpoint = os.environ["ASTRA_DB_API_ENDPOINT"]
token = os.environ["ASTRA_DB_APPLICATION_TOKEN"]
astra_db_namespace = os.environ.get("ASTRA_DB_KEYSPACE")  # optional

#  Initialize an Embedding Driver.
```

(continues on next page)

(continued from previous page)

```
embedding_driver = OpenAiEmbeddingDriver(api_key=os.environ["OPENAI_API_KEY"])

vector_store_driver = AstraDbVectorStoreDriver(
    embedding_driver=embedding_driver,
    api_endpoint=api_endpoint,
    token=token,
    collection_name="griptape_test_collection",
    astra_db_namespace=astra_db_namespace,  # optional
)

#  Load Artifacts from the web

artifact = WebLoader().load("https://www.griptape.ai")
chunks = TextChunker().chunk(artifact)

#  Upsert Artifacts into the Vector Store Driver

vector_store_driver.upsert_collection({"griptape": chunks})

results = vector_store_driver.query(query="What is griptape?")

values = [r.to_artifact().value for r in results]

print("\n\n".join(values))
```

PG.AI

The PgAiKnowledgeBaseVectorStoreDriver integrates with PG.AI, a managed postgres platform from EnterpriseDB .

Here is an example of how the Driver can be used to load and query information in a PG.AI Knowledge Base:

```
import os

from griptape.drivers.vector.pgai import PgAiKnowledgeBaseVectorStoreDriver

#  PG.AI connection parameters

connection_string = os.environ["PGAI_CONNECTION_STRING"]
knowledge_base_name = os.environ["PGAI_KNOWLEDGE_BASE_NAME"]

vector_store_driver = PgAiKnowledgeBaseVectorStoreDriver(
    connection_string=connection_string,
    knowledge_base_name=knowledge_base_name,  # optional
)

results = vector_store_driver.query(query="What is griptape?")

values = [r.to_artifact().value for r in results]

print("\n\n".join(values))
```

Web Scraper

Overview

Web Scraper Drivers can be used to scrape text from the web. They are used by *WebLoader* to provide its functionality. All Web Scraper Drivers implement the following methods:

- `scrape_url()` scrapes text from a website and returns a *TextArtifact* . The format of the scrapped text is determined by the Driver.

Web Scraper Drivers

Proxy

The *ProxyWebScraperDriver* uses the `requests` library with a provided set of proxies to do web scraping. Paid webscraping services like ZenRows or ScraperAPI offer a way to use their API via a set of proxies passed to `requests.get()`

Example using `ProxyWebScraperDriver` directly:

```
import os

from griptape.drivers.web_scraper.proxy import ProxyWebScraperDriver

query_params = [
    "markdown_response=true",
    "js_render=false",
    "premium_proxy=false",
]
proxy_url = f"http://{os.environ[ZENROWS_API_KEY]}:{&.join(query_params)}@proxy.
↪zenrows.com:8001"

driver = ProxyWebScraperDriver(
    proxies={
        "http": proxy_url,
        "https": proxy_url,
    },
    params={"verify": False},
)

driver.scrape_url("https://griptape.ai")
```

Markdownify

To install the playwright browsers, run `playwright install` in your terminal. If you are using uv, run `uv run playwright install` instead. The `playwright` command should already be installed as a dependency of the `drivers-web-scraper-markdownify` extra. For more details about playwright, see the playwright docs .

Note that if you skip installing the playwright browsers, you will see the following error when you run your code:

```
playwright._impl._errors.Error: Executable doesnt exist at ...
╔═══════════════════════════════════════════════════════════╗
║ Looks like Playwright was just installed or updated.      ║
║ Please run the following command to download new browsers: ║
║                                                           ║
```

(continues on next page)

(continued from previous page)

```
╟     playwright install                                                    ╢
╟                                                                           ╢
╟ <3 Playwright Team                                                       ╢
╚═══════════════════════════════════════════════════════════════════════════╝
```

The *MarkdownifyWebScraperDriver* outputs the scraped text in markdown format. It uses playwright to render web pages along with dynamically loaded content, and a combination of beautifulsoup4 and markdownify to produce a markdown representation of a webpage. It makes a best effort to produce a markdown representation of a webpage that is concise yet human (and LLM) readable.

Example using `MarkdownifyWebScraperDriver` directly:

```
from griptape.drivers.web_scraper.markdownify import MarkdownifyWebScraperDriver

driver = MarkdownifyWebScraperDriver()

driver.scrape_url("https://griptape.ai")
```

Example of using `MarkdownifyWebScraperDriver` with an agent:

```
from griptape.drivers.web_scraper.markdownify import MarkdownifyWebScraperDriver
from griptape.loaders import WebLoader
from griptape.structures import Agent
from griptape.tools import WebScraperTool

agent = Agent(
    tools=[
        WebScraperTool(
            web_loader=WebLoader(web_scraper_
↪driver=MarkdownifyWebScraperDriver(timeout=1000)),
            off_prompt=False,
        ),
    ],
)
agent.run("List all email addresses on griptape.ai in a flat numbered markdown list.")
```

Trafilatura

The *TrafilaturaWebScraperDriver* scrapes text from a webpage using the Trafilatura library.

Example of using `TrafilaturaWebScraperDriver` directly:

```
from griptape.drivers.web_scraper.trafilatura import TrafilaturaWebScraperDriver

driver = TrafilaturaWebScraperDriver()

driver.scrape_url("https://griptape.ai")
```

Web Search

Overview

Web Search Drivers can be used to search for links from a search query. They are used by *BaseWebSearchDriver* to provide its functionality. All Web Search Drivers implement the following methods:

- `search()` searches the web and returns a *ListArtifact* that contains JSON-serializable *TextArtifact* s with the search results.

You can use Web Search Drivers with *Structures* :

```
from griptape.drivers.web_search.duck_duck_go import DuckDuckGoWebSearchDriver
from griptape.structures import Agent
from griptape.tools import PromptSummaryTool, WebSearchTool

agent = Agent(
    tools=[WebSearchTool(web_search_driver=DuckDuckGoWebSearchDriver()),␣
↪PromptSummaryTool(off_prompt=False)],
)

agent.run("Give me some websites with information about AI frameworks.")
```

```
PromptTask 45a53f1024494baab41a1f10a67017b1
    Output: Here are some websites with information about AI
    frameworks:

      1. [The Top 16 AI Frameworks and Libraries: A Beginners Guide -      ␣
↪DataCamp](https://www.datacamp.com/blog/top-ai-frameworks-and-lib      raries)
      2. [AI Frameworks: Top Types To Adopt in 2024 -      Splunk](https://www.splunk.
↪com/en_us/blog/learn/ai-frameworks.htm      l)
      3. [Top AI Frameworks in 2024: A Review -      BairesDev](https://www.bairesdev.
↪com/blog/ai-frameworks/)
      4. [The Top 16 AI Frameworks and Libraries - AI      Slackers](https://

```

Web Search Drivers

Google

The *GoogleWebSearchDriver* uses the *Google Custom Search JSON API* for web searching.

```
import os

from griptape.drivers.web_search.google import GoogleWebSearchDriver

driver = GoogleWebSearchDriver(
    api_key=os.environ["GOOGLE_API_KEY"],
    search_id=os.environ["GOOGLE_API_SEARCH_ID"],
)

driver.search("griptape ai")
```

DuckDuckGo

The *DuckDuckGoWebSearchDriver* uses the duckduckgo_search SDK for web searching.

```
from griptape.drivers.web_search.duck_duck_go import DuckDuckGoWebSearchDriver

driver = DuckDuckGoWebSearchDriver()

driver.search("griptape ai")
```

Tavily

```
import os

from griptape.drivers.web_search.tavily import TavilyWebSearchDriver

driver = TavilyWebSearchDriver(api_key=os.environ["TAVILY_API_KEY"])

driver.search("griptape ai")
```

Exa

```
import os

from griptape.drivers.web_search.exa import ExaWebSearchDriver

```

(continues on next page)

(continued from previous page)

```
driver = ExaWebSearchDriver(api_key=os.environ["EXA_API_KEY"])

driver.search("griptape ai")
```

Perplexity

The *PerplexityWebSearchDriver* uses the *Perplexity Prompt Driver* internally.

```
import os

from griptape.drivers.web_search.perplexity import PerplexityWebSearchDriver

driver = PerplexityWebSearchDriver(
    api_key=os.environ["PERPLEXITY_API_KEY"],
)
result = driver.search("griptape ai")

print(result.to_text())

#  The search results will only contain a single Artifact.

#  This Artifact contains the search results and any citations.

for citation in result[0].meta["citations"]:
    print(citation)
```

`

2. Set up your OpenAI API key:

```
export OPENAI_API_KEY=your_api_key_here
```

3. Create a Python file (e.g., `app.py`) and import necessary modules from Griptape[3].
4. Build your AI application using Griptape's components such as agents, pipelines, and tools[3].

Griptape offers a powerful and flexible way to create AI-driven applications, from simple chatbots to complex multi-agent systems. Its modular approach allows developers to easily integrate custom tools and external resources, enhancing the capabilities of AI agents[3][4]. https://www.griptape.ai https://github.com/griptape-ai https://www.youtube.com/watch?v=AEcztigpnc0 https://www.youtube.com/watch?v=1FFeMZyWxJA https://github.com/griptape-ai/griptape https://www.youtube.com/@griptape-ai

````

## 11.3 RAG Engine

### 11.3.1 RAG Engines

*RAG Engine* is an abstraction for implementing modular retrieval augmented generation (RAG) pipelines.
````

RAG Stages

`RagEngine` s consist of three *stages*: `QueryRagStage` , `RetrievalRagStage` , and `ResponseRagStage` . These stages are always executed sequentially. Each stage comprises multiple *modules*, which are executed in a customized manner. Due to this unique structure, `RagEngines` are not intended to replace *Workflows* or *HuggingFace Pipelines* .

RAG Modules

RAG modules are used to implement actions in the different stages of the RAG pipeline. `RagEngine` enables developers to easily add new modules to experiment with novel RAG strategies.

The three stages of the pipeline implemented in RAG Engines, together with their purposes and associated modules, are as follows:

Query Stage

This stage is used for modifying input queries before they are submitted.

Query Stage Modules

- `TranslateQueryRagModule` is for translating the query into another language.

Retrieval Stage

Results are retrieved in this stage, either from a vector store in the form of chunks, or with a text loader. You may optionally use a rerank module in this stage to rerank results in order of their relevance to the original query.

Retrieval Stage Modules

- `TextChunksRerankRagModule` is for re-ranking retrieved results.
- `TextLoaderRetrievalRagModule` is for retrieving data with text loaders in real time.
- `VectorStoreRetrievalRagModule` is for retrieving text chunks from a vector store.

Response Stage

Responses are generated in this final stage.

Response Stage Modules

- `PromptResponseRagModule` is for generating responses based on retrieved text chunks.
- `TextChunksResponseRagModule` is for responding with retrieved text chunks.
- `FootnotePromptResponseRagModule` is for responding with automatic footnotes from text chunk references.

RAG Context

`RagContext` is a container object for passing around queries, text chunks, module configs, and other metadata. `RagContext` is modified by modules when appropriate. Some modules support runtime config overrides through `RagContext.module_configs` .

Simple Example

The following example shows a simple RAG pipeline that retrieves data from a local vector store and generates a response:

```
from griptape.chunkers import TextChunker
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver
from griptape.drivers.vector.local import LocalVectorStoreDriver
from griptape.engines.rag import RagContext, RagEngine
from griptape.engines.rag.modules import (
    PromptResponseRagModule,
    VectorStoreRetrievalRagModule,
)
from griptape.engines.rag.stages import (
    ResponseRagStage,
    RetrievalRagStage,
)
from griptape.loaders import WebLoader

vector_store = LocalVectorStoreDriver(embedding_driver=OpenAiEmbeddingDriver())

#  Load some data from a couple sources.

web_artifact = WebLoader().load("https://griptape.ai")
chunks = TextChunker(max_tokens=250).chunk(web_artifact)
vector_store.upsert_collection({"griptape": chunks})

rag_engine = RagEngine(
    # This stage is responsible for retrieving the relevant chunks.
    retrieval_stage=RetrievalRagStage(
        retrieval_modules=[
            VectorStoreRetrievalRagModule(
                name="WebRetriever",
                vector_store_driver=vector_store,
                query_params={"namespace": "griptape"},
            ),
        ],
    ),
    # This stage is responsible for generating the final response.
    response_stage=ResponseRagStage(
        response_modules=[
            PromptResponseRagModule(),
        ]
    ),
)

rag_context = RagContext(query="What is Griptape?")
rag_context = rag_engine.process(rag_context)
print(rag_context.outputs[0].to_text())
```

Advanced Example

The following example shows an advanced RAG pipeline that does the following:

- Translates incoming queries into English.
- Retrieves data from a local vector store and a local file.
- Reranks the results using the local rerank driver.

- Generates multiple types of response.

```
from rich.pretty import pprint

from griptape.chunkers import TextChunker
from griptape.common.reference import Reference
from griptape.drivers.embedding.openai import OpenAiEmbeddingDriver
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.drivers.rerank.local import LocalRerankDriver
from griptape.drivers.vector.local import LocalVectorStoreDriver
from griptape.engines.rag import RagContext, RagEngine
from griptape.engines.rag.modules import (
    FootnotePromptResponseRagModule,
    PromptResponseRagModule,
    TextChunksRerankRagModule,
    TextChunksResponseRagModule,
    TextLoaderRetrievalRagModule,
    TranslateQueryRagModule,
    VectorStoreRetrievalRagModule,
)
from griptape.engines.rag.stages import (
    QueryRagStage,
    ResponseRagStage,
    RetrievalRagStage,
)
from griptape.loaders import TextLoader, WebLoader
from griptape.rules import Rule, Ruleset

prompt_driver = OpenAiChatPromptDriver(model="gpt-4.1")
vector_store = LocalVectorStoreDriver(embedding_driver=OpenAiEmbeddingDriver())
rerank_driver = LocalRerankDriver()
web_loader = WebLoader()
text_chunker = TextChunker(max_tokens=250)

#  Load some data from a couple sources.

sites = [
    {
        "title": "Griptape Site",
        "url": "https://www.griptape.ai",
    },
    {"title": "Griptape GitHub", "url": "https://github.com/griptape-ai/griptape"},
]
site_artifacts = list(web_loader.load_collection([site["url"] for site in sites]).
↪values())

#  Set a reference on each artifact so that the FootnotePromptResponseRagModule can␣
↪generate footnotes.

for site_arifact, site in zip(site_artifacts, sites):
    site_arifact.reference = Reference(title=site["title"], url=site["url"])

#  Chunk each site artifact.
```

(continues on next page)

(continued from previous page)

```
site_artifacts_chunks = [text_chunker.chunk(artifact) for artifact in site_artifacts]

#  Flatten the list of chunks before inserting them into the vector store.

site_artifacts_chunks = [
    site_artifact_chunk for site_artifact_chunk in site_artifacts_chunks for site_
↪artifact_chunk in site_artifact_chunk
]
vector_store.upsert_collection({"griptape": site_artifacts_chunks})

rag_engine = RagEngine(
    # This stage is responsible for producing the query. It can include things like␣
↪translation, rewriting, etc.
    query_stage=QueryRagStage(query_modules=[TranslateQueryRagModule(prompt_
↪driver=prompt_driver, language="english")]),
    # This stage is responsible for retrieving the relevant chunks.
    retrieval_stage=RetrievalRagStage(
        max_chunks=5,
        retrieval_modules=[  # Modules can pull from different sources.
            # Such as a vector store
            VectorStoreRetrievalRagModule(
                name="WebRetriever",
                vector_store_driver=vector_store,
                query_params={"top_n": 20, "namespace": "griptape"},
            ),
            # Or a text source.
            TextLoaderRetrievalRagModule(
                loader=TextLoader(),
                vector_store_driver=vector_store,
                source="README.md",
            ),
        ],
        # We can rerank the chunks before passing them to the response stage to␣
↪ensure the best ones are used.
        rerank_module=TextChunksRerankRagModule(rerank_driver=LocalRerankDriver()),
    ),
    # This stage is responsible for generating the final response.
    response_stage=ResponseRagStage(
        response_modules=[
            # You can have multiple response modules to generate different types of␣
↪responses.
            PromptResponseRagModule(
                prompt_driver=prompt_driver,
                rulesets=[Ruleset(name="Concise", rules=[Rule("Answer concisely")])],
            ),
            # This one generates a response with footnotes.
            FootnotePromptResponseRagModule(prompt_driver=prompt_driver),
            # This one just returns the text chunks directly with no LLM generation.
            TextChunksResponseRagModule(),
        ]
    ),
```

(continues on next page)

(continued from previous page)

```
)

rag_context = RagContext(
    query="¿Qué ofrecen los servicios en la nube de Griptape?",  # What do Griptapes␣
↪cloud services offer?
)
rag_context = rag_engine.process(rag_context)

#  Lets print out the interesting responses

for output in rag_context.outputs[:2]:
    print(output.to_text() + "\n")

#  We can also see the references that were configured up-front

pprint(rag_context.get_references())
```

RAG Tool

See *RagTool* for an example of how to integrate the RAG Tool with an Agent.

Eval Engine

Overview

The *Eval Engine* is used to evaluate the performance of an LLM's output against a given input. The engine returns a score between 0 and 1, along with a reason for the score.

Eval Engines require either validate*criteria(*, value) or validate*evaluation_steps(*, value) to be set. If `criteria` is set, Gen AI Builder will generate `evaluation_steps` for you. This is useful for getting started, but you may to explicitly set `evaluation_steps` for more complex evaluations. Either `criteria` or `evaluation_steps` must be set, but not both.

```
import json

from griptape.engines import EvalEngine

engine = EvalEngine(
    criteria="Determine whether the actual output is factually correct based on the␣
↪expected output.",
)

score, reason = engine.evaluate(
    input="If you have a red house made of red bricks, a blue house made of blue␣
↪bricks, what is a greenhouse made of?",
    expected_output="Glass",
    actual_output="Glass",
)

print("Eval Steps", json.dumps(engine.evaluation_steps, indent=2))
print(f"Score: {score}")
print(f"Reason: {reason}")
```

Extraction Engines

Overview

Extraction Engines enable the extraction of structured data from unstructured text. These Engines can be used with Structures via *Extraction Tasks* . As of now, Gen AI Builder supports two types of Extraction Engines: the CSV Extraction Engine and the JSON Extraction Engine.

CSV

The CSV Extraction Engine extracts comma separated values from unstructured text.

```
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.engines import CsvExtractionEngine

#  Initialize the CsvExtractionEngine instance

csv_engine = CsvExtractionEngine(
    prompt_driver=OpenAiChatPromptDriver(model="gpt-3.5-turbo"), column_names=["name",
↪ "age", "location"]
)

#  Define some unstructured data

sample_text = """
Alice, 28, lives in New
York.
Bob, 35 lives in California
Charlie is 40
Collin is 28 and lives in San Francisco
"""

#  Extract CSV rows using the engine

result = csv_engine.extract_text(sample_text)

for row in result:
    print(row.to_text())
```

```
name,age,location
Alice,28,New York
Bob,35,California
Charlie,40,
Collin,28,San Francisco
```

JSON

The JSON Extraction Engine extracts JSON-formatted values from unstructured text.

```
import json

from schema import Literal, Schema

```

(continues on next page)

(continued from previous page)

```python
from griptape.artifacts import ListArtifact
from griptape.chunkers import TextChunker
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.engines import JsonExtractionEngine
from griptape.loaders import WebLoader

#  Define a schema for extraction

json_engine = JsonExtractionEngine(
    prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1"),
    template_schema=Schema(
        {
            Literal("model", description="Name of an LLM model."): str,
            Literal("notes", description="Any notes of substance about the model."):␣
↪Schema([str]),
        }
    ).json_schema("ProductSchema"),
)

#  Load data from the web

web_data = WebLoader().load("https://en.wikipedia.org/wiki/Large_language_model")
chunks = TextChunker().chunk(web_data)

#  Extract data using the engine

result = json_engine.extract_artifacts(ListArtifact(chunks))

for artifact in result:
    print(json.dumps(artifact.value, indent=2))
```

```
{
  "model": "GPT-3.5",
  "notes": [
    "Part of OpenAIs GPT series.",
    "Used in ChatGPT and Microsoft Copilot."
  ]
}
{
  "model": "GPT-4",
  "notes": [
    "Part of OpenAIs GPT series.",
    "Praised for increased accuracy and multimodal capabilities.",
    "Architecture and number of parameters not revealed."
  ]
}
...Output truncated for brevity...
```

Summary Engine

Overview

Summary engines are used to summarize text and collections of *TextArtifact* s.

Prompt

Used to summarize texts with LLMs. You can set a custom *prompt_driver()* , *default_generate_system_template(context, artifacts)* , *default_generate_user_template(query, language)* , and *Chunkers* .

Use the summarize_artifacts(artifacts, *, rulesets=None)abstractmethod method to summarize a list of artifacts or summarize_text(text, *, rulesets=None) to summarize an arbitrary string.

```
import requests

from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.engines import PromptSummaryEngine
from griptape.loaders import PdfLoader

response = requests.get("https://arxiv.org/pdf/1706.03762.pdf")
engine = PromptSummaryEngine(
    prompt_driver=OpenAiChatPromptDriver(model="gpt-3.5-turbo"),
)

artifact = PdfLoader().parse(response.content)

engine.summarize_artifacts(artifact)
```

11.4 Events

11.4.1 Overview

You can configure the global *EventBus* with :ref:``EventListenerDriver.on_event` Return Value Behavior <*EventListenerDriver.on_event* Return Value Behavior>` s to listen for various framework events. See *Event Listener Drivers* for examples on forwarding events to external services.

11.4.2 Specific Event Types

You can listen to specific event types:

```
from griptape.events import (
    BaseEvent,
    EventBus,
    EventListener,
    FinishActionsSubtaskEvent,
    FinishPromptEvent,
    FinishTaskEvent,
    StartActionsSubtaskEvent,
    StartPromptEvent,
    StartTaskEvent,
)
from griptape.structures import Agent
```

(continues on next page)

(continued from previous page)

```
def on_event(event: BaseEvent) -> None:
    print(event.__class__)

EventBus.add_event_listeners(
    [
        EventListener(
            on_event,
            event_types=[
                StartTaskEvent,
                FinishTaskEvent,
                StartActionsSubtaskEvent,
                FinishActionsSubtaskEvent,
                StartPromptEvent,
                FinishPromptEvent,
            ],
        )
    ]
)

agent = Agent()

agent.run("tell me about griptape")
```

11.4.3 All Event Types

Or listen to all events:

```
from griptape.events import BaseEvent, EventBus, EventListener
from griptape.structures import Agent

def handler1(event: BaseEvent) -> None:
    print("Handler 1", event.__class__)

def handler2(event: BaseEvent) -> None:
    print("Handler 2", event.__class__)

EventBus.add_event_listeners(
    [
        EventListener(handler1),
        EventListener(handler2),
    ]
)

agent = Agent()

agent.run("tell me about griptape")
```

11.4.4 Stream Iterator

You can use `Structure.run_stream()` for streaming Events from the `Structure` in the form of an iterator.

> **Tip**
>
> Set *stream=True* on your *Prompt Drivers* in order to receive completion chunk events.

```
from griptape.events import BaseEvent
from griptape.structures import Agent

agent = Agent()

for event in agent.run_stream("Hi!", event_types=[BaseEvent]):  # All Events
    print(type(event))
```

11.4.5 Context Managers

You can also use :ref:`EventListenerDriver.on_event` Return Value Behavior <`EventListenerDriver.on_event` Return Value Behavior>` s as a Python Context Manager. The ``EventListener` will automatically be added and removed from the *EventBus* when entering and exiting the context.

```
from griptape.events import EventBus, EventListener, FinishStructureRunEvent,␣
↪StartPromptEvent
from griptape.structures import Agent

EventBus.add_event_listeners(
    [EventListener(lambda e: print(f"Out of context: {e.type}"), event_
↪types=[StartPromptEvent])]
)

agent = Agent(input="Hello!")

with EventListener(lambda e: print(f"In context: {e.type}"), event_
↪types=[FinishStructureRunEvent]):
    agent.run()

agent.run()
```

11.4.6 Streaming

You can use the *BaseChunkEvent* to stream the completion results from Prompt Drivers.

```
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.events import BaseChunkEvent, EventBus, EventListener
from griptape.structures import Pipeline
from griptape.tasks import PromptTask
from griptape.tools import PromptSummaryTool, WebScraperTool

EventBus.add_event_listeners(
    [
```

(continues on next page)

(continued from previous page)

```
        EventListener(
            lambda e: print(str(e), end="", flush=True),
            event_types=[BaseChunkEvent],
        ),
    ]
)

pipeline = Pipeline()
pipeline.add_tasks(
    PromptTask(
        "Based on https://griptape.ai, tell me what griptape is.",
        prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1", stream=True),
        tools=[WebScraperTool(off_prompt=True), PromptSummaryTool(off_prompt=False)],
    )
)

pipeline.run()
```

You can also use the *TextChunkEvent* and *ActionChunkEvent* to further differentiate the different types of chunks for more customized output.

```
from griptape.drivers.prompt.openai import OpenAiChatPromptDriver
from griptape.events import ActionChunkEvent, EventBus, EventListener, TextChunkEvent
from griptape.structures import Pipeline
from griptape.tasks import PromptTask
from griptape.tools import PromptSummaryTool, WebScraperTool

EventBus.add_event_listeners(
    [
        EventListener(
            lambda e: print(str(e), end="", flush=True),
            event_types=[TextChunkEvent],
        ),
        EventListener(
            lambda e: print(str(e), end="", flush=True),
            event_types=[ActionChunkEvent],
        ),
    ]
)

pipeline = Pipeline()
pipeline.add_tasks(
    PromptTask(
        "Based on https://griptape.ai, tell me what griptape is.",
        prompt_driver=OpenAiChatPromptDriver(model="gpt-4.1", stream=True),
        tools=[WebScraperTool(off_prompt=True), PromptSummaryTool(off_prompt=False)],
    )
)

pipeline.run()
```

If you want Gen AI Builder to handle the chunk events for you, use the *Stream Iterator* utility to automatically wrap *BaseChunkEvent* s in a Python iterator.

The `Stream` utility does not automatically enable streaming on the Drivers that produce `BaseChunkEvent` s. Make sure to enable streaming on the Drivers or else `Stream` will yield no iterations.

```
import logging

from griptape.configs import Defaults
from griptape.structures import Agent
from griptape.tools import PromptSummaryTool, WebScraperTool
from griptape.utils import Stream

#  Hide Griptapes usual output

logging.getLogger(Defaults.logging_config.logger_name).setLevel(logging.ERROR)

agent = Agent(
    input="Based on https://griptape.ai, tell me what griptape is.",
    tools=[
        PromptSummaryTool(off_prompt=True),
        WebScraperTool(off_prompt=False),
    ],
    stream=True,
)

for artifact in Stream(agent).run():
    print(artifact.value, end="", flush=True)
```

Sometimes, streaming can be too verbose. You can use `Stream.event_types` to only listen to specific event types. A good example is to remove the `ActionChunkEvent` from the stream if you don't need to see events related to Tool usage.

```
import logging

from griptape.configs import Defaults
from griptape.events import FinishPromptEvent, FinishStructureRunEvent, TextChunkEvent
from griptape.structures import Agent
from griptape.tools import PromptSummaryTool, WebScraperTool
from griptape.utils import Stream

#  Hide Griptapes usual output

logging.getLogger(Defaults.logging_config.logger_name).setLevel(logging.ERROR)

agent = Agent(
    input="Based on https://griptape.ai, tell me what griptape is.",
    tools=[
        PromptSummaryTool(off_prompt=True),
        WebScraperTool(off_prompt=False),
    ],
    stream=True,
)

#  Listen for the following event types

event_types = [TextChunkEvent, FinishPromptEvent, FinishStructureRunEvent]
```

(continues on next page)

(continued from previous page)

```
for artifact in Stream(agent, event_types=event_types).run():
    print(artifact.value, end="", flush=True)
```

11.4.7 Counting Tokens

To count tokens, you can use Event Listeners and the *TokenCounter* util:

```
- -8<-- "docs/griptape-framework/misc/src/events_5.py"
```

11.4.8 Inspecting Payloads

You can use the *StartPromptEvent* to inspect the Prompt Stack and final prompt string before it is sent to the LLM.

```
- -8<-- "docs/griptape-framework/misc/src/events_6.py"
```

```
...
Prompt Stack Messages:
system:
user: Write me a poem.
Final Prompt String:

User: Write me a poem.

Assistant:
...
```

11.4.9 `EventListenerDriver.on_event` Return Value Behavior

The value that gets returned from the :ref:`EventListener.on_event` is None <`EventListener.on_event` is None>` will determine what gets sent to the ``event_listener_driver`.

`EventListener.on_event` is None

By default, the `EventListener.on_event` function is `None`. Any events that the `EventListener` is listening for will get sent to the `event_listener_driver` as-is.

Return `BaseEvent` or `dict`

You can return a `BaseEvent` or `dict` object from `EventListener.on_event`, and it will get sent to the `event_listener_driver`.

Return `None`

You can return `None` in the on_event function to prevent the event from getting sent to the `event_listener_driver`.

```
- -8<-- "docs/griptape-framework/misc/src/events_no_publish.py"
```

Serialization

Overview

Many components in Gen AI Builder can be serialized and deserialized using the to_dict(*, types_overrides=None, serializable_overrides=None) and from_dict(data, *, types_overrides=None, serializable_overrides=None)classmethod methods. There are also *value_to_json(value)classmethod* and from_json(data, *, types_overrides=None, serializable_overrides=None)classmethod as a convenience.

Here is how we can serialize an `Agent` and then deserialize it back:

```
from griptape.structures import Agent

agent = Agent()
agent.run("My name is Collin")

agent_dict = agent.to_dict()

new_agent = Agent.from_dict(agent_dict)

new_agent.run("Whats my name?")
```

Serialization Overrides

All classes that implement the *SerializableMixin* can be serialized using the above methods. However, only fields marked with `metadata={"serializable": True}` will be included in the serialization process. If you need to add or remove fields in the serialization process, you can pass *serialization_overrides* to any of the serialization methods.

```
from rich.pretty import pprint

from griptape.structures import Agent

agent = Agent()
agent.run("My name is Collin")

agent_dict = agent.to_dict(serializable_overrides={"max_meta_memory_entries": True,
↪"id": False})

#  `max_meta_memory_entries` will be included, `id` will not

pprint(agent_dict)
```

Types Overrides

Due to some unfortunate internals of the Gen AI Builder's serialization process, you may occasionally run into a `NameError` when serializing. It will look something like this:

This is something we're actively working on fixing, but in the meantime, you can use the from_dict(data, *, types_overrides=None, serializable_overrides=None)classmethod parameter to pass in a dictionary of types that need to be overridden during serialization.

Here is an example of how you can use `types_overrides` :

```
from duckduckgo_search import DDGS
from rich.pretty import pprint
```

(continues on next page)

(continued from previous page)

```
from griptape.drivers.web_search import BaseWebSearchDriver
from griptape.drivers.web_search.duck_duck_go import DuckDuckGoWebSearchDriver
from griptape.tools import WebSearchTool

web_driver = DuckDuckGoWebSearchDriver()
web_tool = WebSearchTool(web_search_driver=web_driver)

web_tool_dict = web_tool.to_dict(
    serializable_overrides={"web_search_driver": True},
    types_overrides={"BaseWebSearchDriver": BaseWebSearchDriver, "DDGS": DDGS},
)

pprint(web_tool_dict)
```

Tokenizers

Overview

Tokenizers are used throughout Gen AI Builder to calculate the number of tokens in a piece of text. They are particularly useful for ensuring that the LLM token limits are not exceeded.

Tokenizers are a low level abstraction that you will rarely interact with directly.

Tokenizers

OpenAI

```
from griptape.tokenizers import OpenAiTokenizer

tokenizer = OpenAiTokenizer(model="gpt-4.1")

print(tokenizer.count_tokens("Hello world!"))
print(tokenizer.count_input_tokens_left("Hello world!"))
print(tokenizer.count_output_tokens_left("Hello world!"))
```

Cohere

```
import os

from cohere import Client

from griptape.tokenizers import CohereTokenizer

tokenizer = CohereTokenizer(model="command", client=Client(os.environ["COHERE_API_KEY
↪"]))

print(tokenizer.count_tokens("Hello world!"))
print(tokenizer.count_input_tokens_left("Hello world!"))
print(tokenizer.count_output_tokens_left("Hello world!"))
```

Anthropic

```
from griptape.tokenizers import AnthropicTokenizer

tokenizer = AnthropicTokenizer(model="claude-3-opus-20240229")

print(tokenizer.count_tokens("Hello world!"))
print(tokenizer.count_input_tokens_left("Hello world!"))
print(tokenizer.count_output_tokens_left("Hello world!"))
```

Google

```
import os

from griptape.tokenizers import GoogleTokenizer

tokenizer = GoogleTokenizer(model="gemini-2.0-flash", api_key=os.environ["GOOGLE_API_
↪KEY"])

print(tokenizer.count_tokens("Hello world!"))
print(tokenizer.count_input_tokens_left("Hello world!"))
print(tokenizer.count_output_tokens_left("Hello world!"))
```

Hugging Face

```
from griptape.tokenizers import HuggingFaceTokenizer

tokenizer = HuggingFaceTokenizer(
    model="sentence-transformers/all-MiniLM-L6-v2",
    max_output_tokens=512,
)

print(tokenizer.count_tokens("Hello world!"))
print(tokenizer.count_input_tokens_left("Hello world!"))
print(tokenizer.count_output_tokens_left("Hello world!"))
```

Amazon Bedrock

```
from griptape.tokenizers import AmazonBedrockTokenizer

tokenizer = AmazonBedrockTokenizer(model="amazon.titan-text-express-v1")

print(tokenizer.count_tokens("Hello world!"))
print(tokenizer.count_input_tokens_left("Hello world!"))
print(tokenizer.count_output_tokens_left("Hello world!"))
```

Grok

```
import os

```

(continues on next page)

(continued from previous page)

```
from griptape.tokenizers import GrokTokenizer

tokenizer = GrokTokenizer(
    model="grok-2-latest",
    api_key=os.environ["GROK_API_KEY"],
)

print(tokenizer.count_tokens("Hello world!"))
print(tokenizer.count_input_tokens_left("Hello world!"))
print(tokenizer.count_output_tokens_left("Hello world!"))
```

Simple

Not all LLM providers have a public tokenizer API. In this case, you can use the `SimpleTokenizer` to count tokens based on a simple heuristic.

```
from griptape.tokenizers import SimpleTokenizer

tokenizer = SimpleTokenizer(max_input_tokens=1024, max_output_tokens=1024, characters_
↪per_token=6)

print(tokenizer.count_tokens("Hello world!"))
print(tokenizer.count_input_tokens_left("Hello world!"))
print(tokenizer.count_output_tokens_left("Hello world!"))
```

prompt_stack_to_string(prompt_stack)

Converts a Prompt Stack to a string for token counting or model prompt_input.

This base implementation is only a rough approximation, and should be overridden by subclasses with model-specific tokens.

Parameters

Name	Type	Description	Default
prompt_stack	<a href="../common#griptape.common.PromptStack" title="PromptStack (griptape.common.PromptStack)"><code class="language-pythc	The Prompt Stack to convert to a string. 	*required*

Returns

Type	Description
str	A single string representation of the Prompt Stack.

Source Code in griptape/drivers/prompt/base_prompt_driver.py

```
def prompt_stack_to_string(self, prompt_stack: PromptStack) -> str:
    """Converts a Prompt Stack to a string for token counting or model prompt_input.

    This base implementation is only a rough approximation, and should be overridden␣
↪by subclasses with model-specific tokens.

    Args:
        prompt_stack: The Prompt Stack to convert to a string.

    Returns:
        A single string representation of the Prompt Stack.
    """
